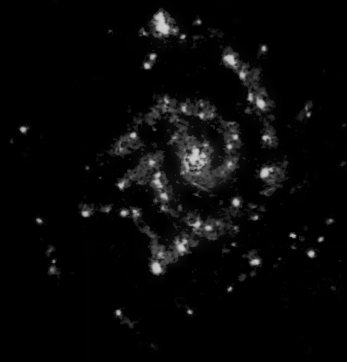
Scientific and Technical Aerospace Reports



An Abstract Journal

Volume 32, Number 3
March 1994
N94-14908 to N94-17677

The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the International Aerospace Database, managed by the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

Front Matter
A typical citation and abstract sample explaining the standard format, which includes codes for ordering reports.

An Abstract Section
Citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.

An Index Section
- Subject
- Personal author
- Corporate source
- Contract number
- Report number.

Appendix
A guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors companion journals, *International Aerospace Abstracts (IAA)*, and *NASA Open Volumes on Aerospace (NOVA)*. They list abstracts of the open literature on aerospace subjects available worldwide. IAA is available from the American Institute of Aeronautics and Astronautics (AIAA), and *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Reports found in *STAR* are also available through the NASA online retrieval service, RECON, and the Aerospace Database through DIALOG.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **853**

02 AERODYNAMICS **855**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **862**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **863**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **865**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **868**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **868**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **870**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **871**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **873**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **874**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **875**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **878**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **879**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **883**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **884**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **899**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **923**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **929**

24 COMPOSITE MATERIALS **930**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **942**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **954**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **962**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **975**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **976**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **983**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **986**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **1007**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **1016**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **1031**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **1037**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **1045**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **1049**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **1056**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **1063**

43 EARTH RESOURCES AND REMOTE SENSING **1081**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **1091**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **1094**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **1097**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **1105**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **1111**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **1115**

52 AEROSPACE MEDICINE **1119**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **1131**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **1134**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY **1139**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **1140**

60 COMPUTER OPERATIONS AND HARDWARE **1140**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **1141**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **1157**
Includes computer networks and special application computer systems.

63 CYBERNETICS **1163**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **1168**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **1172**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **1174**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **1174**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **1175**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **1176**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **1179**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **1187**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **1189**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **1200**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **1205**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **1219**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **1221**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **1222**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **1226**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **1235**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY **1235**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **1235**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) ..... **N.A.**

89 ASTRONOMY **1236**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **1239**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **1246**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **1298**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **1300**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

Scientific and Technical Aerospace Reports

A Monthly Publication of the National Aeronautics and Space Administration

01 AERONAUTICS (GENERAL)

N94-14965# Federal Aviation Administration, Washington, DC. Office of Aviation Policy and Plans.
US CIVIL AIRMEN STATISTICS: CALENDAR YEAR 1992
Jun. 1993 156 p
(AD-A267708; FAA-APO-93-6) Avail: CASI HC A08/MF A02

This report contains calendar year statistics on pilots and nonpilots and the number of certificates issued. It also contains a count of pilots and nonpilots by state and county. DTIC

N94-15120# National Aerospace Lab., Amsterdam (Netherlands).
SYMPOSIUM ON THE FUTURE OF AERONAUTICS IN THE NETHERLANDS [DE TOEKOMST VAN NEDERLAND IN DE LUCHTVAART]
1991 167 p In DUTCH Symposium held in Delft, Netherlands, 26 Apr. 1991
(ETN-93-93780) Avail: CASI HC A08/MF A02

The history of fifty years of the Netherlands Association of Aeronautical Engineers, and the predicted and real developments in the aviation in the period 1961-1991 are depicted. The future of the Schiphol airport and the developments in the European air traffic control are presented. The tasks and prospects of aviation inspection are discussed. The expectations for the future KLM, Fokker the National Aerospace Laboratory, and military aviation in The Netherlands are treated. Developments in the Higher Technical Aerospace Education in the Netherlands and at the Faculty of Aeronautics and Astronautics of the Technical University of Delft are described. For individual titles, see N94-15121 through N94-15131.

N94-15121# Netherlands Association of Aeronautical Engineers, Amsterdam.
FIFTY YEARS OF THE NETHERLANDS ASSOCIATION OF AERONAUTICAL ENGINEERS [VIJFTIG JAAR NVVL: EEN TERUGBLIK]
F. J. Sterk *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 7 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A02/MF A02

The history of fifty years of the Netherlands Association of Aeronautical Engineers is depicted. The guidelines for the foundation of the Association are given. The main activity of the Association was and still is the organization of lectures, symposia, and conferences. ESA

N94-15122# Technische Univ., Delft (Netherlands). Faculteit der Luchtvaart- en Ruimtevaarttechniek.
PREDICTED AND REAL DEVELOPMENT IN THE AVIATION IN THE PERIOD 1961-1991 [VOORSPELDE EN WERKELIJKE ONTWIKKELINGEN IN DE VERKEERSLUCHTVAART (1961-1991)]
H. Wittenberg *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 43 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A03/MF A02

The predictions in developments in aeronautical techniques and aviation given at a symposium in 1966 are taken in a retrospective view and compared with the real developments in the period 1961-1991. It is concluded that the expectations run too high. With respect to technical developments this could be due to the belief in the 'technology push' rather then in the 'market demand'. In general, predictions have to consider social factors ('scenario techniques'). The development of aviation is influenced by many factors, and many efforts are still required to allow predictions based on models. ESA

N94-15123# Netherlands Association of Aeronautical Engineers, Amsterdam.
THE FUTURE OF SCHIPHOL: GROWTH WITHIN BOUNDARIES [DE TOEKOMST VAN SCHIPHOL: GROEIEN BINNEN GRENZEN] **c09**
R. denBesten *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 16 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A03/MF A02

The planned, controlled growth of the Schipol airport considering clear environmental boundary conditions is discussed. Within the tendency of concentration in the European aviation, Schipol tries to become one of the mainports ('hubs') on which intercontinental air traffic concentrates. The planned expansions of the airport and the consequences for the employment and the environment are outlined. ESA

N94-15124# Rijksluchtvaartdienst, The Hague (Netherlands).
DEVELOPMENTS IN THE EUROPEAN AIR TRAFFIC CONTROL [ONTWIKKELINGEN IN DE EUROPESE LUCHTVERKEERSBEVEILIGING] **c04**
J. P. F. deKoning *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 16 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A03/MF A02

Present and future developments in the Air Traffic Control (ATC) are presented. The integrated Eurocontrol ATC operational concept is outlined. The future air traffic control services are presented. The integrated concept includes the combination of civil and military systems. The different system functions have to be compared and possibly adapted. ESA

N94-15125# Rijksluchtvaartdienst, Schiphol (Netherlands).
AVIATION INSPECTION PROSPECTS [TOEKOMSTVERWACHTING RLD, LUCHTVAARTINSPECTIE] **c03**
H. N. Wolleswinkel *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 22 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A03/MF A02

The main tasks of aviation inspection, namely guaranteeing safety and minimizing the environment effects of civil aviation as well as the expectations, are discussed. The activities and methods are strongly changing due to increasing internationalization and environment consciousness. The establishment and application of international rules are outlined. ESA

N94-15126# KLM Aerocarto, Schiphol (Netherlands).
AVIATION AND THE KLM: PAST AND FUTURE [DE LUCHTVAART EN DE KLM: VERLEDEN EN TOEKOMST] **c99**
C. denHartog *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 7 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A02/MF A02

Some aspects of the seventy years of history and of the future of KLM are discussed. Some examples are given to illustrate that the history of KLM is a good reflection of civil aviation as a whole. The expected technological innovations, international strategic airline alliances, and the significance of civil aviation for the Netherlands are outlined. ESA

N94-15127# Fokker B.V., Amsterdam (Netherlands).
EXPECTATIONS FOR THE FUTURE OF FOKKER [TOEKOMSTVERWACHTINGEN FOKKER]
M. vanderVeen *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 3 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A01/MF A02

The perspectives of the Fokker Aircraft Company are outlined. The main emphasis is on civil regional airlines for 50 to 130 passengers; although, participation in Dutch military projects remains important. Until the year 2000 the emphasis is on the extension of the Fo50 and Fo100 aircraft. After 2000 the emphasis will be on aviation deregulation, environmental issues, integrated flight management, and integrated transportation systems. ESA

N94-15128# Ministry of Defence, The Hague (Netherlands).
EXPECTATIONS FOR THE FUTURE OF MILITARY AVIATION [TOEKOMSTVERWACHTINGEN MILITAIRE LUCHTVAART]
Rudolf J. W. Merison *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 12 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A03/MF A02

An overview is given of the existing possibilities in the Netherlands in the field of defense oriented aeronautics and astronautics research and development, with emphasis on the Royal Air Force. From a national military strategic point of view there is a growing need for a European defense industry in which The Netherlands can contribute. The program EUCLID (European Cooperation for the Long term in Defense) was started to integrate the defense developments in Europe. ESA

N94-15129# National Aerospace Lab., Amsterdam (Netherlands).

Avail: CASI HC A03/MF A02

Developments in the Higher Technical Aerospace Education in the Netherlands since 1986 are described. The tasks of high schools in general and of higher aerospace technical education in particular are depicted. The developments in the speciality and in the execution of the profession of the higher aerospace technical engineer is described. The developments in the education process are outlined. The profession of teacher at a higher technical school is sketched. The developments in the relations between higher technical schools on the one hand and universities and industry on the other hand are described including the international dimension. ESA

N94-15131# Technische Univ., Delft (Netherlands). Faculteit der Luchtvaart- en Ruimtevaarttechniek.
EXPECTATIONS FOR THE FUTURE OF THE FACULTY OF AERONAUTICS AND ASTRONAUTICS OF THE TECHNICAL UNIVERSITY OF DELFT [TOEKOMSTVERWACHTINGEN FACULTEIT DER LUCHTVAART- EN RUIMTEVAARTTECHNIEK TU-DELFT] **c80**
T. deJong *In* NAL, Symposium on the Future of Aeronautics in the Netherlands 1991 9 p In DUTCH (For primary document see N94-15120 03-01)
Avail: CASI HC A02/MF A02

The developments at the Faculty of Aeronautics and Astronautics of the TU Delft are described. The purpose of the Faculty is the education of engineers in all the fields of aeronautics and astronautics. The structure of the education and the important role of postdoctoral education are outlined. The intensive international cooperation in the fields of education and research is very important for the future, and the faculty has to maintain its position which is unique in the Netherlands. ESA

N94-15798*# National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.
NAS TECHNICAL SUMMARIES: NUMERICAL AERODYNAMIC SIMULATION PROGRAM, MARCH 1991 - FEBRUARY 1992
1992 266 p Original contains color illustrations
(NASA-TM-109335; NAS 1.15:109335) Avail: CASI HC A12/MF A03; 176 functional color pages

NASA created the Numerical Aerodynamic Simulation (NAS) Program in 1987 to focus resources on solving critical problems in aeroscience and related disciplines by utilizing the power of the most advanced supercomputers available. The NAS Program provides scientists with the necessary computing power to solve today's most demanding computational fluid dynamics problems and serves as a pathfinder in integrating leading-edge supercomputing technologies, thus benefiting other supercomputer centers in Government and industry. This report contains selected scientific results from the 1991-92 NAS Operational Year, March 4, 1991 to March 3, 1992, which is the fifth year of operation. During this year, the scientific community was given access to a Cray-2 and a Cray Y-MP. The Cray-2, the first generation supercomputer, has four processors, 256 megawords of central memory, and a total sustained speed of 250 million floating point operations per second. The Cray Y-MP, the second generation supercomputer, has eight processors and a total sustained speed of one billion floating point operations per second. Additional memory was installed this year, doubling capacity from 128 to 256 megawords of solid-state storage-device memory. Because of its higher performance, the Cray Y-MP delivered approximately 77 percent of the total number of supercomputer hours used during this year. Author (revised)

OVERVIEW OF THE FAA/DCA/NLR PROGRAMS RELATED TO AGEING AIRCRAFT
Harold H. Ottens and J. Ben deJonge 16 Mar. 1993 24 p Presented at International Workshop on Structural Integrity of Ageing Airplanes, Atlanta,

GA, 31 Mar. - 3 Apr. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TR-92119-U; ETN-93-94786) Avail: CASI HC A03

An overview of the research currently carried out at the National Aerospace Laboratory (NLR) (The Netherlands), with regard to the problems of ageing aircraft, is given. This research is primarily directed towards the prevention of ageing aircraft problems in future aircraft and is concentrated in two areas: prevention of multiple site damage in lap joints; improved knowledge in operational load experience. The major part of this research is carried out in some form of international cooperation. The Memorandum of Cooperation between Federal Aviation Administration and the Netherlands Civil Aviation Department in the area of aviation safety provides an effective framework for the coordination of research efforts related to ageing aircraft problems. NLR experiences with this cooperation and support from FAA are very stimulating. ESA

02 AERODYNAMICS

THE EFFECT OF THE NOSE SHAPE AND WING LOCATION TOWARD THE WING VORTEX BREAKDOWN
Feng Yanan, Xia Xuejian, and Liu Rizhi 16 Jul. 1993 14 p Transl. into ENGLISH from Hangkong Xuebao (China), v. 11, no. 12, 1990 p 588-591
(AD-A267724; FASTC-ID(RS)T-0735-92) Avail: CASI HC A03/MF A01

The variation of the wing vortex breakdown vs. the angle of attack for a missile with a cruciform set of wings was investigated through experiments. The tests were carried out by conducting the flow pattern visualization in the water channel at BUAA. The model had two nose shapes - pointed and blunted nose. The wing was set at fore or aft location along the axis of the body. The experimental results indicate that for the configuration with the same nose, the location of the vortex breakdown for the wing with aft location is closer to the wing trailing edge than that of the wing with fore location. While for the configuration with the wing at an aft location, the wing vortex breakdown for the blunt nose is delayed compared to that for the pointed nose. DTIC

UNSTEADY SEPARATED FLOWS: EMPIRICAL MODEL AND CONTROL Final Report, 1 Aug. 1988 - 31 Dec. 1992
Marvin Luttges and Michael Robinson 7 Jun. 1993 29 p
(Grant AF-AFOSR-0272-88)
(AD-A267282; AFOSR-93-0466TR) Avail: CASI HC A03/MF A01

Research examined the similarity behavior between forced unsteady separated flows elicited by airfoils and delta wings. For the first time, all of the existing unsteady separation data reported in open literature was assembled and contrasted directly. A vortex model which predicted vortex development and shedding characteristics from first principles was developed. Preliminary work was also initiated in using neural network techniques to model and predict these nonlinear unsteady flows. DTIC

THE TURBULENT WALL JET Final Report, Nov. 1991 - 1992
I. Wygnanski and M. D. Zhou 18 May 1993 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0176-88)
(AD-A267675; AFOSR-93-0485TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The flow of a wall jet embedded in an external stream or in a quiescent surrounding fluid was investigated experimentally. It was determined that the flow scales with the excess momentum injected into the stream and the viscosity of the fluid rather than the jet efflux velocity and the dimension of the nozzle. In the presence of an external stream, a velocity ratio parameter R = (Ui - U)/(Uj + U) had to be added in order to obtain a universal scaling of this flow. Low-amplitude external excitation of the wall jet resulted in a reduction of skin friction and drag. The only possible cause for this behavior observed is the enhancement of the two-dimensionality of the large eddies as expressed by spanwise coherence and correlation measurements. DTIC

LASER DOPPLER VELOCIMETRY MEASUREMENTS ACROSS A NORMAL SHOCK IN TRANSONIC FLOW M.S. Thesis
David A. Perretta 25 Mar. 1993 117 p
(AD-A267240) Avail: CASI HC A06/MF A02

One-dimensional laser-Doppler velocimetry measurements were taken with standard optics in back scatter mode across a normal shock at a Mach number of 1.35. Back pressure on a blow-down supersonic tunnel was controlled to place a normal shock in a 4 by 4 inch test section and schlieren visualization techniques were used to verify and record shock position and behavior. Velocity surveys were taken across the shock, using various filtering techniques, in an attempt to quantify shock unsteadiness. Additional surveys were performed to further characterize the flow in the test section. The velocity surveys upstream and downstream of the shock compared favorably with pressure and temperature data and normal shock relations. Surveys across the shock indicated distinct and repeatable velocity patterns, and the measured location of the shock matched schlieren photographs. DTIC

AN UNCERTAINTY ANALYSIS OF INLET DYNAMIC FLOW DISTORTION USING AN ANALOG/DIGITAL HYBRID EDITING SYSTEM Final Report, Feb. 1991 - Dec. 1992
Maryann Zelenak Mar. 1993 337 p
(AD-A266924; ASC-TR-93-5005) Avail: CASI HC A15/MF A03

The objectives of this analysis were to establish precision and bias errors for an analog/digital hybrid computer system (DYNADEC) used in the dynamic data editing phase of inlet wind tunnel testing. An uncertainty analysis was initiated to evaluate the system using inlet data from the Aeronautical Systems Center (ASC)/Arnold Engineering Development Center (AEDC) Freejet Development program. Three test points from a subscale freejet test and three test points from a wind tunnel test of the same F-15 inlet model were selected to cover a wide range of test conditions and turbulence levels. Precision errors of the 40 total pressure probes at the location of the engine face were 1-2% of the 40 total pressure recovery magnitudes. Precision errors of the Pratt and Whitney K a2 distortion index, the parameter used to edit the data on DYNADEC, were also investigated. These results indicated that K a2 precision errors decreased with higher turbulence levels. Static bias errors were also computed by sending known signal through the DYNADEC system and measuring the output quantity. Static bias errors were much smaller in comparison to the precision error magnitudes and may be considered negligible. DTIC

AERODYNAMIC CONTROL OF NASP-TYPE VEHICLES THROUGH VORTEX MANIPULATION. VOLUME 1: STATIC WATER TUNNEL TESTS
Carlos J. Suarez, T. Terry Ng, Lih-Yenn Ong, and Gerald N. Malcolm Sep. 1993 88 p Sponsored by NASA, Washington
(Contract NAS2-13196)
(NASA-CR-177626-Vol-1; A-93138-Vol-1; NAS 1.26:177626-Vol-1) Avail: CASI HC A05/MF A01

Water tunnel tests were conducted on a NASP-type configuration to evaluate different pneumatic Forebody Vortex Control (FVC) methods. Flow visualization and yawing moment measurements were performed at angles of attack from 0 deg to 30 deg. The pneumatic techniques tested included jet and slot blowing. In general, blowing can be used efficiently to manipulate the forebody vortices at angles of attack greater than 20 deg. These vortices are naturally symmetric up to alpha = 25 deg and asymmetric between 25 deg and 30 deg angle of attack. Results indicate that tangential aft jet blowing is the most promising method for this configuration. Aft jet blowing produces a yawing moment towards the blowing side and the trends with blowing rate are well behaved. The size of the nozzle is not the dominant factor in the blowing process; the change in the blowing 'momentum,' i.e., the product of the mass flow rate and the velocity of the jet, appears to be the important parameter in the water tunnel (incompressible

and unchoked flow at the nozzle exit). Forward jet blowing is very unpredictable and sensitive to mass flow rate changes. Slot blowing (with the exception of very low blowing rates) acts as a flow 'separator'; it promotes early separation on the blow side, producing a yawing moment toward the non-blowing side for the C(sub mu) range investigated.

SUPPRESSION OF DYNAMIC STALL WITH A LEADING-EDGE SLAT ON A VR-7 AIRFOIL
K. W. McAlister and C. Tung Mar. 1993 71 p
(RTOP 505-61-51)
(NASA-TP-3357; ATCOM-TR-92-A-013; A-93006; NAS 1.60:3357) Avail: CASI HC A04/MF A01

The VR-7 airfoil was experimentally studied with and without a leading-edge slat at fixed angles of attack from 0 deg to 30 deg at Re = 200,000 and for unsteady pitching motions described by alpha equals alpha(sub m) + 10 deg(sin(wt)). The models were two dimensional, and the test was performed in a water tunnel at Ames Research Center. The unsteady conditions ranged over Re equals 100,000 to 250,000, k equals 0.001 to 0.2, and alpha(sub m) = 10 deg to 20 deg. Unsteady lift, drag, and pitching-moment measurements were obtained along with fluorescent-dye flow visualizations. The addition of the slat was found to delay the static-drag and static-moment stall by about 5 degrees and to eliminate completely the development of a dynamic-stall vortex during unsteady motions that reached angles as high as 25 degrees. In all of the unsteady cases studied, the slat caused a significant reduction in the force and moment hysteresis amplitudes. The reduced frequency was found to have the greatest effect on the results, whereas the Reynolds number had little effect on the behavior of either the basic or the slatted airfoil. The slat caused a slight drag penalty at low angles of attack, but generally increased the lift/drag ratio when averaged over the full cycle of oscillation. Author (revised)

AERODYNAMIC CONTROL OF NASP-TYPE VEHICLES THROUGH VORTEX MANIPULATION. VOLUME 2: STATIC WIND TUNNEL TESTS
Carlos J. Suarez, Brian R. Kramer, Brooke C. Smith, and Gerald N. Malcolm Sep. 1993 144 p Sponsored by NASA, Washington
(Contract NAS2-13196)
(NASA-CR-177626-Vol-2; A-93138-Vol-2; NAS 1.26:177626-Vol-2) Avail: CASI HC A07/MF A02

Forebody Vortex Control (FVC) was explored in this research program for potential application to a NASP-type configuration. Wind tunnel tests were conducted to evaluate a number of jet blowing schemes. The configuration tested has a slender forebody and a 78 deg swept delta wing. Blowing jets were implemented on the leeward side of the forebody with small circular tubes tangential to the surface that could be directed aft, forward, or at angles in between. The effects of blowing are observed primarily in the yawing and rolling moments and are highly dependent on the jet configuration and the angle of attack. Results show that the baseline flow field, without blowing activated, is quite sensitive to the geometry differences of the various protruding jets, as well as being sensitive to the blowing, particularly in the angle of attack range where the forebody vortices are naturally asymmetric. The time lag of the flow field response to the initiation of blowing was also measured. The time response was very short, on the order of the time required for the flow disturbance to travel the distance from the nozzle to the specific airframe location of interest at the free stream velocity. Overall, results indicate that sizable yawing and rolling moments can be induced with modest blowing levels. However, direct application of this technique on a very slender forebody would require thorough wind tunnel testing to optimize the jet location and configuration.

PARTICLE KINETIC SIMULATION OF HIGH ALTITUDE HYPERVELOCITY FLIGHT Report, 1 Jan. - 31 Aug. 1993
Brian L. Haas 12 Oct. 1993 58 p
(Contract NCC2-582)
(NASA-CR-194599; NAS 1.26:194599) Avail: CASI HC A04/MF A01

In this grant period, the focus has been on enhancement and application of the direct simulation Monte Carlo (DSMC) particle method for computing hypersonic flows of re-entry vehicles. Enhancement efforts dealt with modeling gas-gas interactions for thermal non-equilibrium relaxation processes and gas-surface interactions for prediction of vehicle surface temperatures. Both are important for application to problems of engineering interest. The code was employed in a parametric study to improve future applications, and in simulations of aeropass maneuvers in support of the Magellan mission. Detailed comparisons between continuum models for internal energy relaxation and DSMC models reveals that several discrepancies exist. These include definitions of relaxation parameters and the methodologies for implementing them in DSMC codes. These issues were clarified and all differences were rectified in a paper (Appendix A) submitted to Physics of Fluids A, featuring several key figures in the DSMC community as co-authors and B. Haas as first author. This material will be presented at the Fluid Dynamics meeting of the American Physical Society on November 21, 1993. The aerodynamics of space vehicles in highly rarefied flows are very sensitive to the vehicle surface temperatures. Rather than require prescribed temperature estimates for spacecraft as is typically done in DSMC methods, a new technique was developed which couples the dynamic surface heat transfer characteristics into the DSMC flow simulation code to compute surface temperatures directly. This model, when applied to thin planar bodies such as solar panels, was described in AIAA Paper No. 93-2765 (Appendix B) and was presented at the Thermophysics Conference in July 1993. The paper has been submitted to the Journal of Thermophysics and Heat Transfer. Application of the DSMC method to problems of practical interest requires a trade off between solution accuracy and computational expense and limitations. A parametric study was performed and reported in AIAA Paper No. 93-2806 (Appendix C) which assessed the accuracy penalties associated with simulations of varying grid resolution and flow domain size. The paper was also presented at the Thermophysics Conference and will be submitted to the journal shortly. Finally, the DSMC code was employed to assess the pitch, yaw, and roll aerodynamics of the Magellan spacecraft during entry into the Venus atmosphere at off-design attitudes. This work was in support of the Magellan aerobraking maneuver of May 25-Aug. 3, 1993. Furthermore, analysis of the roll characteristics of the configuration with canted solar panels was performed in support of the proposed 'Windmill' experiment. Results were reported in AIAA Paper No. 93-3676 (Appendix D) presented at the Atmospheric Flight Mechanics Conference in August 1993, and were submitted to Journal of Spacecraft and Rockets. Author

WIND TUNNEL INVESTIGATION OF THREE AXISYMMETRIC COWLS OF DIFFERENT LENGTHS AT MACH NUMBERS FROM 0.60 TO 0.92
Richard J. Re and William K. Abeyounis Sep. 1993 285 p Sponsored by NASA, Washington
(RTOP 535-03-10-01)
(NASA-TM-4488; L-17191; NAS 1.15:4488) Avail: CASI HC A13/MF A03

Pressure distributions on three inlets having different cowl lengths were obtained in the Langley 16-Foot Transonic Tunnel. The cowl diameter ratio (highlight diameter to maximum diameter) was 0.85 and the cowl length ratios (cowl length to maximum diameter) were 0.337, 0.439, and 0.547. The cowls had identical nondimensionalized (with respect to cowl length) external geometry and identical internal geometry. The internal contraction ratio (highlight area to throat area) was 1.250. The inlets had longitudinal rows of static pressure orifices on the top and bottom (external) surfaces and on the contraction (internal) and diffuser surfaces. The afterbody was cylindrical in shape, and its diameter was equal to the maximum diameter of the cowl. Depending on the cowl configuration and free-stream Mach number, the mass-flow ratio varied between 0.27 and 0.87 during the tests. Angle of attack varied from 0 to 4.1 deg at selected Mach numbers and mass-flow ratios, and the Reynolds number varied with the Mach number from 3.2x10(exp 6) to 4.2x10(exp 6) per foot. HEAT TRANSFER AND AERODYNAMICS OF A 3D DESIGN NOZZLE GUIDE VANE TESTED IN THE PYESTOCK ISENTROPIC LIGHT PISTON FACILITY
K. S. Chana 17 Dec. 1992 15 p Presented at the AGARD 80th

Symposium of the Propulsion and Energetics Panel on Heat Transfer and Cooling in Gas Turbines, Antalaya, Turkey, 12-16 Oct. 1992 Original contains color illustrations
(RAE-TM-Aero/Prop-19; BR316026; ETN-93-94495) Copyright Avail: CASI HC A03/MF A01

The prediction of the heat transfer to the blade and endwalls in high pressure turbines, which is particularly important for an accurate assessment of turbine component life is addressed. On the endwalls, there are often complex three dimensional (3D) (secondary) flows present which make predictions of heat transfer particularly difficult. A detailed investigation of this area was carried out on a fully annular cascade of highly 3D nozzle guide vanes. Measurements were made on the vane and endwalls to determine heat transfer and aerodynamic characteristics. Testing was conducted in a short duration isentropic light piston test facility, at engine representative Reynolds number, Mach number, and gas to wall temperature ratio. Interpreted test data are compared with computations obtained at test conditions. ESA

AERODYNAMIC CONTROL OF NASP-TYPE VEHICLES THROUGH VORTEX MANIPULATION, VOLUME 4
Brooke C. Smith, Carlos J. Suarez, William M. Porada, and Gerald N. Malcolm Sep. 1993 151 p Sponsored by NASA, Washington
(Contract NAS2-13196)
(NASA-CR-177626-Vol-4; A-93138; NAS 1.26:177626-Vol-4) Avail: CASI HC A08/MF A02

Forebody Vortex Control (FVC) is an emerging technology that has received widespread and concentrated attention by many researchers for application on fighter aircraft to enhance aerodynamic controllability at high angles of attack. This research explores potential application of FVC to a NASP-type configuration. The configuration investigated is characterized by a slender, circular cross-section forebody and a 78 deg swept delta wing. A man-in-the-loop, six-degress-of-freedom, high-fidelity simulation was developed that demonstrates the implementation and advantages of pneumatic forebody vortex control. Static wind tunnel tests were used as the basis for the aerodynamic characteristics modeled in the simulation. Dynamic free-to-roll wind tunnel tests were analyzed and the wing rock motion investigated. A non-linear model of the dynamic effects of the bare airframe and the forebody vortex control system were developed that closely represented the observed behavior. Multiple state-of-the-art digital flight control systems were developed that included different utilizations of pneumatic vortex control. These were evaluated through manned simulation. Design parameters for a pneumatic forebody vortex control system were based on data collected regarding the use of blowing and the mass flow required during realistic flight maneuvers. Author (revised)

AERODYNAMIC CONTROL OF NASP-TYPE VEHICLES THROUGH VORTEX MANIPULATION. VOLUME 3: WING ROCK EXPERIMENTS
Carlos J. Suarez, Brooke C. Smith, Brian R. Kramer, T. Terry Ng, Lih-Yenn Ong, and Gerald N. Malcolm Sep. 1993 130 p
(Contract NAS2-13196)
(NASA-CR-177626; A-93138; NAS 1.26:177626) Avail: CASI HC A07/MF A02

Free-to-roll tests were conducted in water and wind tunnels in an effort to investigate the mechanisms of wing rock on a NASP-type vehicle. The configuration tested consisted of a highly-slender forebody and a 78 deg swept delta wing. In the water tunnel test, extensive flow visualization was performed and roll angle histories were obtained. In the wind tunnel test, the roll angle, forces and moments, and limited forebody and wing surface pressures were measured during the wing rock motion. A limit cycle oscillation was observed for angles of attack between 22 deg and 30 deg. In general, the experiments confirmed that the main flow phenomena responsible for the wing-body-tail wing rock are the interactions between the forebody and the wing vortices. The variation of roll acceleration (determined from the second derivative of the roll angle time history) with roll angle clearly slowed the energy balance necessary to sustain the limit cycle oscillation. Different means of suppressing wing rock by controlling the forebody vortices using small blowing jets were also explored. Steady blowing was found to be capable of suppressing wing rock, but significant vortex asymmetrices are created, causing the model to stop at a non-zero roll angle. On the other hand, alternating pulsed blowing on the left and right sides of the fore body was demonstrated to be a potentially effective means of suppressing wing rock and eliminating large asymmetric moments at high angles of attack. PARTICLE SIMULATION OF HYPERSONIC FLOW Final Report, 1 Apr. 1990 - 31 Mar. 1993
Donald Baganoff 26 May 1993 40 p
(Grant AF-AFOSR-0232-90)
(AD-A267185; AFOSR-93-0457TR) Avail: CASI HC A03/MF A01

A particle code for simulating a rarefied hypersonic flow is developed which accounts for a multiple species gas in thermochemical nonequilibrium and which takes advantage of the parallel architecture of the Intel iPSC/860 supercomputer. Various tests were conducted using a generic blunt body consisting of a hemispherically blunted 60-degree half-angle cone at angle of attack. The different tests conducted show that the performance of the parallel code using 512 nodes exceeds by an order of magnitude the performance obtained for a highly vectorized code run on a single processor of the Cray YMP, that scaleup is found to be nearly linear with the number of processors used, that run time can be greatly reduced by employing a large number of particles, and that runs with 67.5 million particles can be carried out when employing the large memory of the Intel iPSC/860. Other results relate to different applications of the code for studying the near-continuum state of a gas near a cold solid boundary. DTIC

CENTER FOR ROTORCRAFT EDUCATION AND RESEARCH PROGRESS REPORT, 1987 - 1992 Final Report, 1 Jan. 1988 - 31 Dec. 1992
Inderjit Chopra Jun. 1993 133 p
(Contract DAAL03-88-C-0002)
(AD-A266760; ARO-25467.74-EG-RW) Avail: CASI HC A07/MF A02

Established in 1981, the Center for Rotorcraft Education and Research at the University of Maryland has achieved international recognition as a center of excellence in rotorcraft engineering based on the quality and quantity of its research output and advanced-degree recipients. In the process of growth, it has built an integrated team of rotorcraft dedicated research faculty and staff, a pipeline of high quality graduate students, and a group of specialized rotorcraft research facilities and instrumentation unmatched by any other university. The center carried out interdisciplinary research program built around four interrelated areas that advanced understanding and predictive capability in: Aerodynamics-unsteady aerodynamics, dynamic stall, and rotor/airframe interaction tests and analyses; Dynamics and Aeroelasticity-bearingless and composite rotor tests and analyses, and minimization of rotor/body vibrations by optimization techniques; Flight Dynamics and Control-control of the dynamic behavior of highly coupled rotor-fuselage configurations; and Structures and Materials-structural integrity, energy absorption, and modeling of composite blades. A RAPID COMPUTATIONAL MODEL FOR ESTIMATING THE PERFORMANCE OF COMPLIANT AIRFOILS IN CASCADES Technical Report, Jan. - Jun. 1992
F. Sisto and M. Avila 1 Jul. 1992 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A266275; NPS-AA-93-001) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We consider the problem of designing the blades in a turbomachine to have a specific schedule of structural stiffness in order to achieve more favorable aerothermodynamic performance characteristics than is possible with rigid blades. This problem of 'aerothermodynamic tailoring' is extremely complex because of the need to couple the flow computation over a deformable surface with the structural dynamics computation. In this report an analysis is presented which accomplishes this objective by means of a two-dimensional incompressible potential flow model using vortex sheet representation of the blades. Details of the analysis and of the resulting computer program together with representative results are described. DTIC

COMPUTATION OF THE FLUID AND OPTICAL FIELDS ABOUT THE STRATOSPHERIC OBSERVATORY FOR INFRARED ASTRONOMY (SOFIA) AND THE COUPLING OF FLUIDS, DYNAMICS, AND CONTROL LAWS ON PARALLEL COMPUTERS Final Report
Christopher A. Atwood May 1993 185 p
(Contract NCC2-677)
(NASA-CR-193168; NAS 1.26:193168; MCAT-93-09) Avail: CASI HC A09/MF A02

The June 1992 to May 1993 grant NCC-2-677 provided for the continued demonstration of Computational Fluid Dynamics (CFD) as applied to the Stratospheric Observatory for Infrared Astronomy (SOFIA). While earlier grant years allowed validation of CFD through comparison against experiments, this year a new design proposal was evaluated. The new configuration would place the cavity aft of the wing, as opposed to the earlier baseline which was located immediately aft of the cockpit. This aft cavity placement allows for simplified structural and aircraft modification requirements, thus lowering the program cost of this national astronomy resource. Three appendices concerning this subject are presented. For individual titles, see N94-16511 through N94-16513.

Atwood *In its* Computation of the Fluid and Optical Fields About the Stratospheric Observatory for Infrared Astronomy (SOFIA) and the Coupling of Fluids, Dynamics, and Control Laws on Parallel Computers May 1993 13 p The 1993 ASME Fluids Engineering Conference of the Forum on Computational Aero- and Hydro-Acoustics held in Washington, DC, 20-24 Jun. 1993 (For primary document see N94-16510 03-02)
Avail: CASI HC A03/MF A02

An efficient diagonal scheme implemented in an overset mesh framework has permitted the analysis of geometrically complex cavity flows via the Reynolds averaged Navier-Stokes equations. Use of rapid hyperbolic and algebraic grid methods has allowed simple specification of critical turbulent regions with an algebraic turbulence model. Comparisons between numerical and experimental results are made in two dimensions for the following problems: a backward-facing step; a resonating cavity; and two quieted cavity configurations. In three-dimensions the flow about three early concepts of the stratospheric Observatory For Infrared Astronomy (SOFIA) are compared to wind-tunnel data. Shedding frequencies of resolved shear layer structures are compared against experiment for the quieted cavities. The results demonstrate the progress of computational assessment of configuration safety and performance. Author (revised)

Christopher A. Atwood *In its* Computation of the Fluid and Optical Fields About the Stratospheric Observatory for Infrared Astronomy (SOFIA) and the Coupling of Fluids, Dynamics, and Control Laws on Parallel Computers May 1993 12 p Conference of the AIAA 24th Fluid Dynamics, PlasmaDynamics, and Lasers held in Orlando, FL, 6-9 Jul. 1993 (For primary document see N94-16510 03-02)
(AIAA Paper 93-3017) Avail: CASI HC A03/MF A02

The time-varying fluid and optical fields of several cavity configurations have been computed on overset mesh systems using the Reynolds-averaged Navier-Stokes equations and geometric optics. Comparisons between numerical results and Airborne Optical Adjunct (AOA) flight data are made in two-dimensions for a quieted cavity geometry with two lip-blowing rates. In three-dimensions, two proposed aero-window locations for the Stratospheric Observatory For Infrared Astronomy (SOFIA) are discussed. The simulations indicate that convection of large shear layer structures across the aperture cause the blur circle diameter to be three times the diffraction-limited diameter in the near-infrared band. Avail: CASI HC A03/MF A02

Coupling of the Reynolds-averaged Navier-Stokes equations, rigid-body dynamics, and a pitch attitude control law is demonstrated in two- and three-dimensions. The application problem was the separation of a canard-controlled store from an open-flow rectangular cavity bay at a freestream Mach number of 1.2. The transient flowfield was computed using a diagonal scheme in an overset mesh framework, with the resultant aerodynamic loads used as the forcing functions in the nonlinear dynamics equations. The proportional and rate gyro sensitivities were computed a priori using pole placement techniques for the linearized dynamical equations. These fixed gain values were used in the controller for the nonlinear simulation. Reasonable comparison between the full and linearized equations for a perturbed two-dimensional missile was found. Also in two-dimensions, a controlled store was found to possess improved separation characteristics over a canard-fixed store. In three-dimensions, trajectory comparisons with wind-tunnel data for the canard-fixed case will be made. In addition, it will be determined if a canard-controlled store is an effective means of improving cavity store separation characteristics. Author (revised)

An axisymmetric panel code and a three dimensional Navier-Stokes code (used as an inviscid Euler code) were verified for low speed, high angle of attack flow conditions. A three dimensional Navier-Stokes code (used as an inviscid code), and an axisymmetric Navier-Stokes code (used as both viscous and inviscid code) were also assessed for high Mach number cruise conditions. The boundary layer calculations were made by using the results from the panel code or Euler calculation. The panel method can predict the internal surface pressure distributions very well if no shock exists. However, only Euler and Navier-Stokes calculations can provide a good prediction of the surface static pressure distribution including the pressure rise across the shock. Because of the high CPU time required for a three dimensional Navier-Stokes calculation, only the axisymmetric Navier-Stokes calculation was considered at cruise conditions. The use of suction and tangential blowing boundary layer control to eliminate the flow separation on the internal surface was demonstrated for low free stream Mach number and high angle of attack cases. The calculation also shows that transition from laminar flow to turbulent flow on the external cowl surface can be delayed by using suction boundary layer control at cruise flow conditions. The results were compared with experimental data where possible. Author

EFFECTS OF INTERNAL YAW-VECTORING DEVICES ON THE STATIC PERFORMANCE OF A PITCH-VECTORING NONAXISYMMETRIC CONVERGENT-DIVERGENT NOZZLE
Scott C. Asbury Washington NASA. Washington Sep. 1993 109 p
(RTOP 505-68-70-06)

An investigation was conducted in the static test facility of the Langley 16-Foot Transonic Tunnel to evaluate the internal performance of a nonaxisymmetric convergent divergent nozzle designed to have simultaneous pitch and yaw thrust vectoring capability. This concept utilized divergent flap deflection for thrust vectoring in the pitch plane and flow-turning deflectors installed within the divergent flaps for yaw thrust vectoring. Modifications consisting of reducing the sidewall length and deflecting the sidewall outboard were investigated as means to increase yaw-vectoring performance. This investigation studied the effects of multiaxis (pitch and

yaw) thrust vectoring on nozzle internal performance characteristics. All tests were conducted with no external flow, and nozzle pressure ratio was varied from 2.0 to approximately 13.0. The results indicate that this nozzle concept can successfully generate multiaxis thrust vectoring. Deflection of the divergent flaps produced resultant pitch vector angles that, although dependent on nozzle pressure ratio, were nearly equal to the geometric pitch vector angle. Losses in resultant thrust due to pitch vectoring were small or negligible. The yaw deflectors produced resultant yaw vector angles up to 21 degrees that were controllable by varying yaw deflector rotation. However, yaw deflector rotation resulted in significant losses in thrust ratios and, in some cases, nozzle discharge coefficient. Either of the sidewall modifications generally reduced these losses and increased maximum resultant yaw vector angle. During multiaxis (simultaneous pitch and yaw) thrust vectoring, little or no cross coupling between the thrust vectoring processes was observed. Author (revised)

WIND TUNNEL INVESTIGATIONS OF FOREBODY STRAKES FOR YAW CONTROL ON F/A-18 MODEL AT SUBSONIC AND TRANSONIC SPEEDS

Gary E. Erickson and Daniel G. Murri Washington NASA. Washington Sep. 1993 101 p
(RTOP 505-68-30-03)
(NASA-TP-3360; L-17197; NAS 1.60:3360) Avail: CASI HC A06/MF A02

Wind tunnel investigations have been conducted of forebody strakes for yaw control on 0.06-scale models of the F/A-18 aircraft at free-stream Mach numbers of 0.20 to 0.90. The testing was conducted in the 7- by 10-Foot Transonic Tunnel at the David Taylor Research Center and the Langley 7- by 10-Foot High-Speed Tunnel. The principal objectives of the testing were to determine the effects of the Mach number and the strake plan form on the strake yaw control effectiveness and the corresponding strake vortex induced flow field. The wind tunnel model configurations simulated an actuated conformal strake deployed for maximum yaw control at high angles of attack. The test data included six-component forces and moments on the complete model, surface static pressure distributions on the forebody and wing leading-edge extensions, and on-surface and off-surface flow visualizations. The results from these studies show that the strake produces large yaw control increments at high angles of attack that exceed the effect of conventional rudders at low angles of attack. The strake yaw control increments diminish with increasing Mach number but continue to exceed the effect of rudder deflection at angles of attack greater than 30 degrees. The character of the strake vortex induced flow field is similar at subsonic and transonic speeds. Cropping the strake planform to account for geometric and structural constraints on the F-18 aircraft has a small effect on the yaw control increments at subsonic speeds and no effect at transonic speeds. WIND-TUNNEL INVESTIGATION OF AERODYNAMIC EFFICIENCY OF THREE PLANAR ELLIPTICAL WINGS WITH CURVATURE OF QUARTER-CHORD LINE

Raymond E. Mineck and Paul M. H. W. Vijgen (High Technology Corp., Hampton, VA.) Washington NASA. Washington Oct. 1993 80 p
(RTOP 505-59-10-03)
(NASA-TP-3359; L-17185; NAS 1.60:3359) Avail: CASI HC A05/MF A01

Three planar, untwisted wings with the same elliptical chord distribution but with different curvatures of the quarter-chord line were tested in the Langley 8-Foot Transonic Pressure Tunnel (8-ft TPT) and the Langley 7- by 10-Foot High-Speed Tunnel (7 x 10 HST). A fourth wing with a rectangular planform and the same projected area and span was also tested. Force and moment measurements from the 8-ft TPT tests are presented for Mach numbers from 0.3 to 0.5 and angles of attack from -4 degrees to 7 degrees. Sketches of the oil-flow patterns on the upper surfaces of the wings and some force and moment measurements from the 7 x 10 HST tests are presented at a Mach number of 0.5. Increasing the curvature of the quarter-chord line makes the angle of zero lift more negative but has little effect on the drag coefficient at zero lift. The changes in lift-curve slope and in the Oswald efficiency factor with the change in curvature of the quarter-chord line (wingtip location) indicate that the elliptical wing with the unswept quarter-chord line has the lowest lifting efficiency and the elliptical wing with the unswept trailing edge has the highest lifting efficiency; the crescent-shaped planform wing has an efficiency in between. HOPH BIFURCATION IN VISCOUS, LOW SPEED FLOWS ABOUT AN AIRFOIL WITH STRUCTURAL COUPLING Ph.D. Thesis

Mark J. Lutton Mar. 1993 152 p
(AD-A266542; AFIT/DS/AA/93-1) Avail: CASI HC A08/MF A02

The locations of Hopf bifurcation points associated with the viscous, incompressible flow about a NACA 0012 airfoil with structural coupling are computed for very low Reynolds numbers (less than 2000). A semi-implicit, first-order-accurate time-integration algorithm is employed to solve the stream-function-vorticity form of the Navier-Stokes equations. The formulation models the inclusion of simple structural elements affixed to the airfoil and captures the resulting airfoil motion. The equations describing the airfoil motion are integrated in time using a fourth-order Runge-Kutta algorithm. The dissertation is divided into two parts. In part one, numerical experiments are performed in the laminar regime to determine if the structural model of the airfoil has an effect upon the location of the Hopf bifurcation point when compared with the fixed airfoil. Results are reported for a variety of structural characteristics including variations of torsional and linear spring constants, inertial properties, structural coupling, and structural damping. The structure of the solution space is explored by means of phase plots. In part two, the Baldwin-Lomax turbulence model is implemented to model turbulent flow. A numerical effort is made to predict the onset of unsteady flow. DTIC

DETERMINING THE EFFECT OF ENDWALL BOUNDARY LAYER SUCTION IN A LARGE SCALE SUBSONIC COMPRESSOR CASCADE M.S. Thesis

Matthew A. Webber 31 Mar. 1993 140 p
(AD-A267208) Avail: CASI HC A07/MF A02

An arrangement of suction slots was installed in the Naval Postgraduate School's subsonic cascade wind tunnel. The aim was to improve flow two dimensionality to enable flow separation of the installed controlled diffusion blades at high incidence. The slots were located 17.25 inches upstream of the test section. Pressure and laser Doppler velocimetry measurements were made, for a Reynolds number of 711000 and an inlet flow angle of 44.4 deg, upstream and downstream of the test section to determine the effects of varying suction. The set of baseline inlet flow field measurements was to be used for comparison purposes in future tunnel modifications. The results showed that the tunnel endwall boundary layers were asymmetric for the baseline configuration. Uniform suction was not achieved in both the pitchwise and spanwise directions. However, the axial velocity ratio was reduced by 1.9 percent and the blade loading increased slightly with increased suction. DTIC

COMPUTATIONAL AERODYNAMICS WITH ICING EFFECTS Ph.D. Thesis
Thomas N. Mouch May 1993 160 p
(AD-A267509; AFIT/CI/CIA-93-007D) Avail: CASI HC A08/MF A02

A quick, inexpensive technique has been developed for the analysis of a full aircraft configuration with iced surfaces. A comprehensive literature search of icing analysis methods is presented. Viscous effects for the flow field about an airfoil with an iced leading edge are accounted for in a thin-layer Navier-Stokes code (ARC2D). A panel code (PMARC) solves the flow field away from the body. The results of the airfoil analysis represent the near-field solutions and are used to modify the boundary conditions in the three-dimensional calculations with the panel code by matching the local circulation. This process is repeated until the total lift coefficient between successive iterations differs by less than a specified value. Comparison with viscous experimental data shows excellent results for lift coefficient and a strong improvement over the basic PMARC for drag and pitching moment coefficients. For the full configuration considered, with ice simulated on the horizontal tail, pitching moment data predicts a very sudden unstable pitch break above angle of attack = 8 deg. This tendency models the pitch tendency described in the literature for similar configurations with an iced horizontal tail. Thus, a quick method has been developed to handle a full configuration with viscous effects. DTIC

After vigorous development for over twenty years, Computational Fluid Dynamics (CFD) in the field of aerospace engineering has arrived at a turning point toward maturity. This paper discusses issues related to algorithm development for the Euler/Navier Stokes equations, code validation and recent applications of CFD for unsteady aerodynamics. Algorithm development is a fundamental element for a good CFD program. Code validation tries to bridge the reliability gap between CFD and experiment. Many of the recent applications also take a multidisciplinary approach, which is a future trend for CFD applications. As computers become more affordable, CFD is expected to be a better scientific and engineering tool. Author

A brief summary of the work done at Yale in the collaborative research program between Yale, Princeton, and Penn State is given. One of the findings of the work is that there is a second-order 'transition' between the low-Reynolds-number boundary layer and the high Reynolds-number boundary layer. The nature of this transition and the elucidation of this mechanism is one of the topics of this research. Other aspects concern the self-similar scaling aspects of the Reynolds shear stress, scaling of the probability density of velocity increments, and the scaling of the multiplier distributions for the energy dissipation. AN EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF LEADING EDGE GEOMETRY ON THE DYNAMICS OF BLUNT FIN-INDUCED SHOCK WAVE TURBULENT BOUNDARY LAYER INTERACTION M.S. Thesis
Kelly Kleifges May 1993 99 p
(AD-A267656; AFIT/CI/CIA-93-093) Avail: CASI HC A05/MF A02

Fluctuating wall pressure measurements have been made on the centerline upstream of blunt fins in a Mach 5 flow. Standard time series analysis and conditional sampling algorithms have been used to examine the effects of leading edge sweep, leading edge shape, and fin root modifications on the RMS level and spectral content of fluctuating pressures. Results show that the fluctuating loads can be reduced significantly by appropriate modification of the fin leading edge. Leading edge sweep considerably reduces the mean and RMS pressure loading at the fin root, the extent of the region of unsteady separation shock motion (i.e. the intermittent region), and the separation length. The spectral content of pressure fluctuations in the intermittent region shifts to higher frequencies with leading edge sweep, while the spectral content of pressure fluctuations in the separated region is virtually unchanged by leading edge sweep. Of the different fin leading edge geometries which induce the same size interaction, the 'blunter' configurations produce smaller intermittent regions and larger separated regions. While the use of a strake at the fin leading edge root has virtually no effect, a swept hemicylindrically blunted root fillet reduces the centerline upstream influence and intermittent region length by 50% and reduces the mean and RMS pressure loading at the fin root by 75% and 95% respectively. SUPERSONIC FLOW VISUALIZATION OF A NACELLE IN CLOSE PROXIMITY TO A SIMULATED WING Final Technical Report
Kasim Biber and David R. Ellis Jul. 1993 43 p
(NASA Order A-24888-D)
(NASA-CR-194675; NAS 1.26:194675; NIAR-93-18) Avail: CASI HC A03/MF A01

A flow visualization study was made in the 9 x 9 inch supersonic wind tunnel at Wichita State University to examine shock and boundary layer flow interaction for a nacelle in close proximity to the lower surface of a simulated wing. The test matrix included variations of angle of attack from -2 degrees to +4 degrees, nacelle-wing gap from 0.5 to 3-nacelle inlet diameter (0.12 inch), and Reynolds number based on nacelle length (1.164 inch) from 1.16 x 10(exp 6) to 1.45 x 10(exp 6) at a nominal Mach number of 2. Schlieren pictures of wing and nacelle flowfield were recorded by a video camera during each tunnel run. Results show that the nacelle inlet shock wave remains attached to the inlet lip and its impingement does not significantly affect the wing boundary layer. At the nacelle trailing edge location, the wing boundary layer thickness is approximately one nacelle inlet diameter at alpha = 0 degrees and it decreases with increase of angle of attack. EXPERIMENTAL STUDY OF VORTEX AND AERODYNAMIC CHARACTERISTICS OF STACK WINGS WITH SIDESLIP
Bao Guohua 20 Jul. 1993 15 p Transl. into ENGLISH from Kongqidonglixue Xuebao (China), v. 7, no. 2, Jun. 1989 p 215-219
(AD-A267722; FASTC-ID(RS)T-0034-93) Avail: CASI HC A03/MF A01

This paper reports on an experimental study of stack wings with small aspect ratio, and describes the variation of detached vortex system at the aircraft wing leading edge with different aspect ratios. The influence on aerodynamic characteristics due to vortex twisting and bursting is analyzed. As revealed in the study, sideslip delays the vortex twisting at the upstream

side of the aircraft wing. The vortex bursts early. At the downward side, the phenomena are exactly in reverse. During sideslip, bursting of an asymmetrical vortex has an obvious influence on the aerodynamic characteristics. DTIC

SUBSONIC AERODYNAMIC CHARACTERISTICS OF THE HL-20 LIFTING-BODY CONFIGURATION
George M. Ware and Christopher I. Cruz Nov. 1993 29 p
(RTOP 505-40-61-01)
(NASA-TM-4515; L-17261; NAS 1.15:4515) Avail: CASI HC A03/MF A01

The HL-20 is proposed as a possible future manned spacecraft. The configuration consists of a low-aspect-ratio body with a flat undersurface. Three fins (a small centerline fin and two outboard (tip) fins set at a dihedral angle of 50 deg) are mounted on the aft body. The control system consists of elevon surfaces on the outboard fins, a set of four body flaps on the upper and lower aft body, and an all-movable center fin. Both the elevons and body flaps were capable of trimming the model to angles of attack from -2 deg to above 20 deg. The maximum trimmed lift-drag ratio was 3.6. Replacing the flat-plate tip fins with airfoil tip fins increased the maximum trimmed lift-drag ratio to 4.2. The elevons were effective as a roll control, but they produced about as much yawing moment as rolling moment because of the tip-fin dihedral angle. The body flaps produced less rolling moment than the elevons and only small values of yawing moment. A limited investigation of the effect of varying tip-fin dihedral angle indicated that a dihedral angle of 50 deg was a reasonable compromise for longitudinal and lateral stability, longitudinal trim, and performance at subsonic speeds. AN EXPERIMENTAL STUDY OF FLUCTUATING WALL PRESSURES IN A HIGHLY SWEPT, SHARP FIN-INDUCED, MACH 5 SHOCK WAVE/TURBULENT BOUNDARY LAYER INTERACTION Final Report, Aug. 1990 - May 1992
J. D. Schmisseur Jan. 1993 158 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2404)
(AD-A268394; WL-TR-93-3058) Avail: CASI HC A08

Fluctuating wall pressure measurements have been made beneath the shock wave/turbulent boundary layer interaction generated by a sharp, unswept fin at angle of attack. Tests were conducted at Mach 5 with a freestream unit Reynolds number of 47.88 x 106 /m. The boundary layer developed naturally on the tunnel floor under approximately adiabatic temperature conditions. From visual inspection and standard time series analysis of fluctuating wall pressure signals, it has been shown that the separation shock wave undergoes a translating, intermittent type motion for fin angles between 16 and 28 degrees. Both the mean wall pressures and higher order moments are quasi-conically symmetric when collapsed in a conical coordinate system. Finally, the maximum wall pressure standard deviation in the intermittent region has been shown to scale with the sweep of the interaction and not with the inviscid pressure rise as has been previously suggested in the literature. The proper use of a computational fluid dynamics code requires a good understanding of the particular code being applied. In this report the application of CFL3D, a thin-layer Navier-Stokes code, is compared with the results obtained from PARC3D, a full Navier-Stokes code. In order to gain an understanding of the use of this code, a simple problem was chosen in which several key features of the code could be exercised. The problem chosen is a cone in supersonic flow at an angle of attack. The issues of grid resolution, grid blocking, and multigridding with CFL3D are explored. The use of multigridding resulted in a significant reduction in the computational time required to solve the problem. Solutions obtained are compared with the results using the full Navier-Stokes equations solver PARC3D. The results obtained with the CFL3D code compared well with the PARC3D solutions. Author

AN INVESTIGATION OF OBLIQUE SHOCK/BOUNDARY LAYER INTERACTION CONTROL Final Report, 1 Dec. 1990 - 31 Mar. 1993
A. Hamed 30 Jun. 1993 14 p
(Grant AF-AFOSR-0101-91)
(AD-A268106; AFOSR-93-0613TR) Avail: CASI HC A03/MF A01

The objective of this work is to provide a basic understanding of the flow in the shock boundary layer interactions and of the mechanisms of their control. A parametric investigation was conducted to determine the effect of bleed configuration on the flow in the interaction region of an incident oblique shock with a turbulent boundary layer. Results of the numerical flow simulations were obtained for different slot widths, depths and slat angles over a bleed mass flow range between zero and choked conditions. The bleed results reveal a complex structure of compression expansion wave system over the bleed port entrance, and different levels of flow operation inside the slot. Code development for the implicit numerical solution of the two dimensional compressible Navier-Stokes and K-Epsilon equations was completed. The code was used in the simulation of unsteady supersonic cavity flow and the results compared with experimental data. DTIC

(AF Proj. 2404)
(AD-A268596; WL-TR-93-3059) Avail: CASI HC A06/MF A02

Off-body flow visualizations and fluid velocity measurements are conducted in a supersonic vortex flow. Three-dimensional laser velocimetry measurements are made in the leeward flowfield over a simple sharp-edged delta wing with 75 degree sweep angle. Tests are conducted at Mach 1.9 and Reynolds number of 2.4 x 10(exp 6) based on model root chord. Measurements are made at 40% and 80% chord positions for 20 and 30 degree angles of attack and at 40% chord for 35 degrees. Mean velocities and turbulence intensities are measured on the five planes. Measurement accuracy is discussed in detail. The measurements define the location of the vortex core and provide the flowfield velocities surrounding the vortex. The difficulties inherent with seeding high velocity vortex flows are discussed. DTIC

DESIGNING CLUTTER REJECTION FILTERS WITH COMPLEX COEFFICIENTS FOR AIRBORNE PULSED DOPPLER WEATHER RADAR Final Technical Report No. 16

Dennis A. Jamora Washington NASA, Washington Oct. 1993 82 p (Grant NAG1-928; RTOP 505-64-12-02)

(NASA-CR-4550; NAS 1.26:4550; DOT/FAA/RD-93/24) Avail: CASI HC A05/MF A01

Ground clutter interference is a major problem for airborne pulse Doppler radar operating at low altitudes in a look-down mode. With Doppler zero set at the aircraft ground speed, ground clutter rejection filtering is typically accomplished using a high-pass filter with real valued coefficients and a stopband notch centered at zero Doppler. Clutter spectra from the NASA Wind Shear Flight Experiments of 1991-1992 show that the dominant clutter mode can be located away from zero Doppler, particularly at short ranges dominated by sidelobe returns. Use of digital notch filters with complex valued coefficients so that the stopband notch can be located at any Doppler frequency is investigated. Several clutter mode tracking algorithms are considered to estimate the Doppler frequency location of the dominant clutter mode. From the examination of night data, when a dominant clutter mode away from zero Doppler is present, complex filtering is able to significantly increase clutter rejection over use of a notch filter centered at zero Doppler. AIRCRAFT ACCIDENT INVESTIGATION AT ARL: THE FIRST 50 YEARS General Document

J. L. Kepert Mar. 1993 107 p

(AD-A267086; ARL-GD-37; DODA-AR-007-134) Avail: CASI HC A06/MF A02

Early Australian experience with the investigation of aircraft accidents is covered briefly as a prelude to the foundation of the Aeronautical Research Laboratory. With its foundation, a more scientific approach was possible. ARL was quickly involved with accident investigation, an activity which has been maintained throughout its fifty year history. This report examines ARL experiences during those fifty years with the idea of providing some useful guidelines for the next half-century. DTIC

ALTITUDE DEVIATIONS: BREAKDOWNS OF AN ERROR-TOLERANT SYSTEM

Everett A. Palmer, Edwin L. Hutchins (California Univ., San Diego.), Richard D. Ritter, and Inge VanCleemput (Wellesley Coll., MA.) Oct. 1993 44 p Sponsored by NASA and FAA, Washington

(RTOP 505-64-13)

(NASA-TM-108788; A-93119; NAS 1.15:108788) Avail: CASI HC A03/MF A01

Pilot reports of aviation incidents to the Aviation Safety Reporting System (ASRS) provide a window on the problems occurring in today's airline cockpits. The narratives of 10 pilot reports of errors made in the automation-assisted altitude-change task are used to illustrate some of the issues of pilots interacting with automatic systems. These narratives are then used to construct a description of the cockpit as an information processing system. The analysis concentrates on the error-tolerant properties of the system and on how breakdowns can occasionally occur. An error-tolerant system can detect and correct its internal processing errors. The cockpit system consists of two or three pilots supported by autoflight, flight-management, and alerting systems. These humans and machines have distributed access to clearance information and perform redundant processing of information. Errors can be detected as deviations from either expected behavior or as deviations from expected information. Breakdowns in this system can occur when the checking and cross-checking tasks that give the system its error-tolerant properties are not performed because of distractions or other task demands. Recommendations based on the analysis for improving the error tolerance of the cockpit system are given.

BASIC PRINCIPLES OF HELICOPTER CRASHWORTHINESS Final Report

Dennis F. Shanahan Feb. 1993 36 p

(DA Proj. 3M1-62787-A-878)

(AD-A267099; USAARL-93-15) Avail: CASI HC A03/MF A01

Crashworthiness can be defined as the ability of an aircraft and its internal systems to protect occupants from injury in the event of a crash. In general, injury in aircraft crashes can be considered to arise from three distinct sources: (1) excessive acceleration forces; (2) direct trauma from contact with hard surfaces; and (3) exposure to environmental factors such as fire, smoke, water, and chemicals resulting in burns, drowning, or asphyxiation. Consequently, effective crashworthiness designs must consider all possible sources of injury and eliminate or mitigate as many as practical for a given design impact limit. This involves considerations of the following: (1) strength of the container (cockpit and cabin); (2) the adequacy of seats and restraint systems; (3) energy attenuation; (4) elimination of injurious objects in occupants local environment; and (5) post-crash factors, principally fire prevention and adequacy of escape routes. The U.S. Army UH-60 Black Hawk and AH-64 Apache helicopters were the first helicopters built to modern crashworthiness specifications. This paper uses data gained from the investigation of crashes of these helicopters to illustrate basic crashworthiness principles and to demonstrate their effectiveness when systematically incorporated into helicopter designs. TECHNICAL URBAN SEARCH AND RESCUE, SYSTEM TO LOCATE SURVIVORS (STOLS) UNITS: OPERATOR'S MANUAL Final Report

May 1993 56 p

(AD-A266317; WES/IR/GL-93-1) Avail: CASI HC A04/MF A01

The U.S. Army Corps of Engineers disaster response can be classified into three phases: (1) Initial; (2) Sustained; and (3) Recovery. The Initial phase is described as the Corps' response in the first 72 hours after the disaster. The Sustained phase may continue for days to weeks depending upon the severity and location of the disaster. The Recovery and final effort continues until the completion of the task. The technical urban search effort for survivors by the Corps of Engineers is categorized in the Initial phase. For effective survivor location, it is necessary to mobilize, deploy, and initialize the search effort in less than 24 hours. It is also necessary for technical search teams to be in a constant state of readiness for the mission. DTIC

NATIONAL TRANSPORTATION SAFETY BOARD ANNUAL REVIEW OF AIRCRAFT ACCIDENT DATA, US GENERAL AVIATION, CALENDAR YEAR 1989
1993 88 p
(PB93-160687; NTSB/ARG-93/01) Avail: CASI HC A05/MF A01

The report presents a statistical compilation and review of general aviation accidents which occurred in 1989 in the United States, its territories and possessions, and in international waters. The accidents reported are all those involving U.S. registered aircraft not conducting operations under 14 CFR 121, 14 CFR 125, 14 CFR 127, or 14 CFR 135. The report is divided into five sections: All Accidents; Fatal Accidents; Serious Injury Accidents; Property Damage Accidents and Midair Collision Accidents. Several tables present accident parameters for 1989 accidents only, and each section includes tabulations which present comparative statistics for 1989 and for the five-year period 1984-1988. NTIS

DEVELOPMENT OF A PROPOSED INTERNATIONAL STANDARD FOR CERTIFICATION OF AIRCRAFT TO HIGH INTENSITY RADIATED FIELDS (HIRF)
Noel B. Sargent Oct. 1993 7 p Proposed for presentation at the 1994 International Pacific Air and Space Technology Conference, Singapore, China, 14-18 Feb. 1994; sponsored by SIAE and SAE
(RTOP 940-30-09-21)
(NASA-TM-106357; E-8141; NAS 1.15:106357) Avail: CASI HC A02/MF A01

Avionic systems performing critical functions in modern aircraft are potentially susceptible to the hazards of electromagnetic radiation from ground and airborne transmitters. The Federal Aviation Administration (FAA) requested that the Society of Automotive Engineers (SAE) coordinate the development of procedures and guidance material which can be used during the aircraft certification process to ensure adequate protection against high intensity radiated fields (HIRF). This paper addresses both the technical challenge of drafting a certification procedure and guidance standard as well as the management process used by the SAE subcommittee AE4R to converge a diverse range of opinions by its international membership in the shortest possible time. THE AIRLINE QUALITY REPORT 1993
Brent D. Bowen (Nebraska Univ., Omaha.) and Dean E. Headly 1993 48 p
(NIAR-93-11) Avail: CASI HC A03/MF A01

The Airline Quality Rating was developed and first announced in early 1991 as an objective method of comparing airline performance on combined multiple factors important to consumers. The Airline Quality Rating 1993 (NIAR Report 93-11) is a summary of month-by-month quality ratings for the nine major domestic U.S. airlines operating during 1992. Using the Airline Quality Rating (AQR) system and monthly performance data for each airline for the calendar year of 1992, individual and comparative ratings are reported. This research monograph contains a brief summary of the AQR methodology, detailed data and charts that track comparative quality for major domestic airlines across the 12 month period of 1992, and results reflecting industry averages. Also, comparative Airline Quality Rating data for 1991 is included to provide a longer term view of quality in the industry. Author (revised)

ANNUAL REVIEW OF AIRCRAFT ACCIDENT DATA. US AIR CARRIER OPERATIONS, CALENDAR YEAR 1990
4 Oct. 1993 74 p
(PB94-102787; NTSB/ARC-93/02) Avail: CASI HC A04/MF A01

This publication presents the record of aviation accidents involving revenue operations of U.S. Air Carriers including Commuter Air Carriers and On Demand Air Taxis for calendar year 1990. The report is divided into three major sections according to the federal regulations under which the flight was conducted - 14 CFR 121, 125, 127, Scheduled 14 CFR 135, or Nonscheduled 14 CFR 135. In each section of the report tables are presented to describe the losses and characteristics of 1990 accidents to enable comparison with prior years. Author

CRIMINAL ACTS AGAINST CIVIL AVIATION, FISCAL YEAR 1992
1992 90 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268014) Avail: CASI HC A05

Civil aviation overall continued to be the object of numerous criminal acts in 1992, but, in those instances where attacks resulted from factors other than personal motivation, the factors tended to be regional, rather than global, in nature. Accordingly, the geographical distribution of incidents varied widely: from a high of 34 in Europe to a low of 4 in North America. Most criminal acts against civil aviation in Asia were the result of internal ethnic or religious confrontations. These included rocket attacks against airports and aircraft by Afghan guerrillas as well as violence against Air India offices in both Bangladesh and Pakistan by Muslims protesting Hindus' destruction of the mosque in Ayodhya, India. For the first year since 1986, there were no projectile attacks against Narita Airport in Japan, the site of attacks and protests since before its construction even began in 1969. Although contractors and politicians associated with the airport continue to be the targets of leftist radicals, Narita Airport has been eclipsed as an issue by the military, the monarchy, and what the leftists term Japanese economic imperialism. The most significant aviation incident in Asia, the hijacking of a Vietnam Airlines aircraft by a former South Vietnamese Air Force pilot living in the U.S., may not bode well for the future as Vietnamese expatriates attempt to frustrate moves by both U.S. companies and the U.S. government to do business with the regime in Hanoi. PANACEA: AN ACTIVE SENSOR CONTROLLER FOR THE ALVINN AUTONOMOUS DRIVING SYSTEM
Rahul Sukthankar, Dean Pomerleau, and Charles Thorpe Apr. 1993 13 p
(Contracts DACA76-89-C-0014; DAAE07-90-C-R059)
(AD-A266964; CMU-RI-TR-93-09) Avail: CASI HC A03/MF A01

Panacea is a modular system which incorporates a steerable sensor into an existing neural network driving system, ALVINN. A fixed camera cannot see the road when it makes sharp bends. For a vision system that builds a map of the road, it is straightforward to point the camera down the road; but ALVINN directly outputs a steering command without generating an intermediate road representation. Insight from the training scheme used in ALVINN, however, provides an interpretation of the steering command in terms of the road geometry and appropriate camera pointing strategies. Tests on the Carnegie Mellon Navlab II with a steerable camera have shown that the system significantly improves ALVINN's performance, particularly in situations requiring sharp turns and quick responses. MASSIVELY PARALLEL, ADAPTIVE, COLOR IMAGE PROCESSING FOR AUTONOMOUS ROAD FOLLOWING
Todd Jochem and Shumeet Baluja May 1993 29 p
(Contracts DACA76-89-C-0014; DAAE07-90-C-R059)
(AD-A266988; CMU-RI-TR-93-10) Avail: CASI HC A03/MF A01

In recent years, significant progress has been made towards achieving autonomous roadway navigation using video images. None of these systems take full advantage of all the information in the 512x512 pixel frame, 30 frame/second color image sequence. This can be attributed to the large amount of data which is present in the color video image stream (22.5 Mbytes/sec) as well as the limited amount of computing resources available to the systems. We have increased the available computing power by using a parallel computer. Specifically, a single instruction, multiple data (SIMD) machine was used to develop simple and efficient parallel algorithms, largely based on connectionist techniques, which can process every pixel in the incoming 30 frame/second, color video image stream. The system uses substantially larger frames and processes them at faster rates than other color road following systems. This is achievable through the use of algorithms specifically designed for a fine-grained parallel machine as opposed to ones ported from existing systems to parallel architectures. The algorithms presented here were tested on 4k and 16k processor MasPar MP-1 and on 4K, 8K, and 16K processor MasPar MP-2 parallel machines and were used to drive Carnegie Mellon's testbed vehicle, the Navlab I, on paved roads near campus. ATCRBS REPLY ENVIRONMENT AT MEMPHIS INTERNATIONAL AIRPORT Project Report
Arnold D. Kaminsky, Katherine M. Hollister, and Martin J. Brennan 28 May 1993 37 p
(Contracts F19628-90-C-0002; DTFA01-93-Z-02012)
(AD-A266322; DOT/FAA/NR-93/3) Avail: CASI HC A03/MF A01

This report demonstrates, through data and analysis, how the airport environment can affect ATCRBS surveillance. The Lincoln Laboratory ATCRBS Monopulse Processing Subsystem was used to collect reply data at Memphis International Airport during Mar. 1991. These data show a correlation between aircraft density, potential reflectors, and ATCRBS reply integrity. The number of replies has been shown to be directly related to multipath from reflecting surfaces including taxiing aircraft. Additionally, it is shown that conditions can exist during which not all of the replies from ATCRBS equipped aircraft can be processed when forming target report measurements. Finally, it is shown that the bunching of replies in both time and space can introduce reply decoder overloading. DTIC

INTERFEROMETRIC GPS ATTITUDE: A STOCHASTIC ERROR MODEL, DREO REPORT
J. C. McMillan Feb. 1993 80 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A266411; DREO-1168) Avail: CASI HC A05

During the August 1992 sea trial off the west coast of Vancouver Island, onboard the CFAV Endeavour, data was collected from a relatively new type of GPS (Global Positioning System) receiver which measures attitude (heading, pitch and roll) as well as the usual GPS measurements of position and velocity. GPS attitude has the potential to provide rapid and precise attitude for a relatively low cost. Attitude is conventionally determined using inertial equipment, which for precise work is very expensive, large and requires a long settling time after turn-on. The receiver being evaluated on this sea trial was an Ashtech Three-Dimensional Direction Finding System (3DF). This report provides some general background on GPS attitude technology, presents the attitude errors observed during this sea trial and characterizes these errors as stochastic processes. DTIC

CATEGORY (CAT) 3B LEVEL 1 TEST PLAN FOR GLOBAL POSITIONING SYSTEM (GPS) Final Report
P. A. ODonnell, R. Braff, and C. A. Shively Sep. 1993 41 p
(Contract DTFA01-93-C-00001)
(DOT/FAA/RD-93/21; MTR-93W0000102) Avail: CASI HC A03/MF A01

The FAA has established a program to demonstrate the feasibility of differential GPS (DGPS) based technology for Category (CAT) IIIb precision approach and landing applications. DGPS includes code corrections and phase differencing or phase correction (real-time kinematic) techniques. Contractors will provide complete systems including ground reference and signal monitor equipment, ground-air data link, and an aircraft instrumented with DGPS receiver/processor driving a flight director/autopilot. Several contractor systems are expected to undergo flight testing and optional satellite simulator testing. This Level 1 plan describes the test concepts and objectives, and also outlines the preparation of Level 2 and Level 3 Test Plans. The primary objective of the flight test is to demonstrate whether a contractor's DGPS system meets either sensor accuracy requirements for CAT IIIb approaches or the total system error requirements of the new tunnel-in-space concept. Additional objectives are to demonstrate adequate integrity and continuity of service. This plan describes specific objectives, guidelines and measures of success (MOS's) for the flight tests. The primary objective of the optional satellite simulator testing is to determine the robustness and integrity characteristics of a contractor's system in response to variations in satellite signals that cannot readily be produced during flight testing. This plan describes specific characteristics to be measured by the satellite simulator testing. Author

WIDE-AREA DIFFERENTIAL GLOBAL POSITIONING SYSTEM (WDGPS)/WIDE-AREA INTEGRITY BROADCAST (WIB) ALTERNATIVES ANALYSIS Final Report
Chris Hegarty, Kelly Markin, and Dan OLaughlin Sep. 1993 44 p
(Contract DTFA01-93-C-00001)
(DOT/FAA/SE-93/3; MTR-93W0000059) Avail: CASI HC A03/MF A01

A study was conducted by MITRE to determine alternative concepts for Wide-area Differential Global Positioning System (WDGPS) for the national airspace system (NAS). The study was undertaken in support of the concept exploration phase analyses required by the Transportation System Acquisition Review Council (TSARC). The results of the study are documented in this paper. The paper provides a description of alternatives to WDGPS, various alternative implementations of WDGPS, advantages and disadvantages of each alternative, and risk areas which were identified. Two WDGPS architecture end-states are recommended. The preferred end-state will depend on the results of required trade-off studies which are identified in this paper. A plan for the transition from the Wide-area Integrity Broadcast (WIB) to the selected WDGPS end-state architecture is also presented. Author

The Airport and Airway Safety, Capacity, Noise Improvement, and Intermodal Transportation Act of 1992 authorized the extension of AIP at a funding level of $2.05 billion through FY 1993. This Act included provisions resulting in a number of changes in AIP. The primary changes include the expanded eligibility of items under the Military Airport Program; eligibility for the relocation of air traffic control towers and navigational aids (including radar) if they impede other projects funded under the AIP; the eligibility of land, paving, drainage, aircraft deicing equipment, and structures for centralized aircraft deicing areas; and projects to comply with the Americans with Disabilities Act of 1990, Clean Air Act, and Federal Water Pollution Control Act. The Act also increases from three to seven the number of states which may participate in the State Block Grant Program and extends the program through FY 1996. DTIC

STATIC AEROELASTIC RESPONSE OF AN AIRCRAFT WITH ASYMMETRIC WING PLANFORMS REPRESENTATIVE OF COMBAT DAMAGE Final Report, Oct. 1991 - Oct. 1992
Jong-Ho Woo Jun. 1993 65 p
(DA Proj. 1L1-62618-AH-80)
(AD-A266890; ARL-TR-153) Avail: CASI HC A04/MF A01

An analysis of the static aeroelastic response of an aircraft with asymmetrical wing planforms representing combat damage is described. The analysis was performed using the MSC/NASTRAN Aeroelastic Code. Structural and aerodynamic models are based on the finite element approach and are created independently for both the damaged and undamaged cases. Fuselage, wings (with aileron), stabilators, and vertical wings (with rudders) are considered as lifting and control surfaces in the aerodynamic model. Five different wings structural models, one undamaged and four damaged, are examined. Doublet-Lattice subsonic theory is used to account for interference effects among multiple lifting surfaces and bodies. The stability and control derivatives, airloads, and trim values are obtained for the damaged-wing aircraft. Effects of damage, including the influence of wing-body interference, on the aircraft's flight dynamics are discussed. DTIC

PARAMETRIC STUDY OF A FINITE ELEMENT MODEL OF THE SIDEWINDER MISSILE M.S. Thesis
Gregory G. VanDyke Mar. 1993 59 p
(AD-A267245) Avail: CASI HC A04/MF A01

The long range Maritime Patrol mission has evolved and expanded such that the U.S. Navy's maritime patrol aircraft (P-3C Orion) has become an attractive platform from which to employ a wide variety of air launched weapons. Specifically the need for a stand alone air-to-air defensive capability was identified. In 1989 the Naval Air Test Center at Patuxent River, Maryland began investigations for this through the P-3C/AIM-9 integration program. Naval Postgraduate School responded to this with the construction of a ground vibration test stand and the conduction of a preliminary vibrational characterization of the AIM-9 missile. From these tests a two degree of freedom lumped mass model was developed along with the determination of the primary and secondary missile resonate modes in pitch. In addition, a mathematical model of the AIM-9 missile was developed using finite element techniques. This model was used to analytically determine the modal parameters of the missile and set up a model test system to experimentally verify the model parameters in view of natural frequencies, mode shapes and transient response. This investigation extends the finite element model utility by refining the model structural code to incorporate an improved mass distribution geometry, thus providing more accurate correspondence between observed natural frequencies and model generated modes and performing a parametric study on the model to discover its sensitivity conformation and material changes. This would anticipate any future missile block upgrades, provide further verification of the finite element model and provide model refinement to more accurately represent the physical structure and behavior. These techniques are inherently missile generic and could, with proper calibration be applied to any weapon to be loaded on any platform. This would provide the Navy with an accurate and cost effective methodology for identifying a potential wing flutter problem prior to ever loading and flying a weapon. DTIC

This report describes the progress and performance by the University of North Dakota under NASA Research Award NAG-1-1351, 'Preliminary Analysis of University of North Dakota Aircraft Data from the FIRE Cirrus IFO-II,' for the period October 15, 1992 to April 14, 1993. Included is a summary of the data archival status and preliminary analysis efforts. During this reporting period, data archival efforts were directed toward providing reduced data for the FIRE data archive and fulfilling special requests for reduced and valued and value-added data. NON-LETHAL UNMANNED AERIAL VEHICLES (UAVs) Final Test Operations Procedure
15 Jun. 1993 43 p Supersedes AD-871331; X70-17501
(AD-A267139; TOP-6-2-040; AD-871331) Avail: CASI HC A03/MF A01

This TOP describes testing methods for determining the technical characteristics of Non-Lethal Unmanned Aerial Vehicles (UAV's). It provides a general description of facilities, instrumentation, and tasks required. It also specifies the documentation required including safety, environmental, and frequency authorization documentation. In details methodology for measuring Center of Gravity, developing flight profiles, performing flight tests, and performing transportability tests. This TOP discusses in general Electromagnetic Environmental, Manpower Integration/Reliability, Availability, Maintainability (MANPRINT/RAM), and Aural/Visual/Acoustic testing. DTIC

THE LIFT-FAN POWERED-LIFT AIRCRAFT CONCEPT: LESSONS LEARNED
Wallace H. Deckert Sep. 1993 79 p Sponsored by NASA, Washington
(NASA Order A-25364-D)
(NASA-CR-177616; A-93107; NAS 1.26:177616) Avail: CASI HC A05/MF A01

This is one of a series of reports on the lessons learned from past research related to lift-fan aircraft concepts. An extensive review is presented of the many lift-fan aircraft design studies conducted by both government and industry over the past 45 years. Mission applications and design integration including discussions on manifolding hot gas generators, hot gas dusting, and energy transfer control are addressed. Past lift-fan evaluations of the Avrocar are discussed. Lessons learned from these past efforts are identified. Author (revised)

PHYSICAL PROPERTIES OF THE BENCHMARK MODELS PROGRAM SUPERCRITICAL WING
Bryan E. Dansberry, Michael H. Durham, Robert M. Bennett, David L. Turnock (Lockheed Engineering and Sciences Co., Hampton, VA.), Walter A. Silva, and Jose A. Rivera, Jr. Washington Sep. 1993 62 p
(RTOP 505-63-50-16)
(NASA-TM-4457; L-17177; NAS 1.15:4457) Avail: CASI HC A04/MF A01

The goal of the Benchmark Models Program is to provide data useful in the development and evaluation of aeroelastic computational fluid dynamics (CFD) codes. To that end, a series of three similar wing models are being flutter tested in the Langley Transonic Dynamics Tunnel. These models are designed to simultaneously acquire model response data and unsteady surface pressure data during wing flutter conditions. The supercritical wing is the second model of this series. It is a rigid semispan model with a rectangular planform and a NASA SC(2)-0414 supercritical airfoil shape. The supercritical wing model was flutter tested on a flexible mount, called the Pitch and Plunge Apparatus, that provides a well-defined, two-degree-of-freedom dynamic system. The supercritical wing model and associated flutter test apparatus is described and experimentally determined wind-off structural dynamic characteristics of the combined rigid model and flexible mount system are included. AN ANALYSIS OF TACTICAL AIRLIFTER CHARACTERISTICS AND THEIR IMPACT ON THEATER AIRLIFT SYSTEM PERFORMANCE M.S. Thesis
John J. Koger Mar. 1993 124 p
(AD-A266719; AFIT/GST/ENS/93M-05) Avail: CASI HC A06/MF A02

This study used computer simulation and Response Surface Technology to determine what tactical airlifter characteristics most impact theater airlift system performance in a Southwest Asia (SWA) scenario. Some Aircraft characteristics were grouped into functional sets, while others were considered individually. After screening one characteristic, reliability, with a two-level factorial experiment, a Box-Behnken design was used to estimate second-order metamodels. A stepwise regression procedure indicated that, if attrition rates are ignored, airlift system performance is most impacted by the aircraft's size, survivability, cruise speed, and ability to operate on short fields. The SWA scenario used in this study covers a large geographical area and varying threat levels and types. The results of this study were compared with those of an earlier study that used the much smaller, low threat Central American scenario. It was determined that across a range of scenarios airlift system performance is most affected by the aircraft's size, survivability, cruise speed, ability to operate on short fields, and ability to operate on unprepared surfaces. ADVANCED COOLING FOR HIGH POWER ELECTRIC ACTUATORS Interim Report, Jan. - Sep. 1992
Michael G. Schneider and Timothy J. Bland Jan. 1993 154 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-91-C-2139)
(AD-A266984; WL-TR-93-2047) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The development of more electric technologies for future military aircraft promises to provide significant redundancy, reliability, maintainability, and performance benefits. Advanced Cooling For High Power Electric Actuators particularly address the use electro-mechanical actuators (EMA's), and an approach for cooling EMA's using the combined concepts of passive reflux cooling and phase change materials (PCM's) for energy storage. The planned program involves four Phases: Phase 1 Requirements and Trade Studies; Phase 2 Detailed Design; Phase 3 Fabrication and Test Plans; and Phase 4 Test/Data Correlation. During Phase 1 Sundstrand identified actuator cooling requirements and evaluated the effects of several critical parameters on the use of passive reflux cooling in combination with PCM. DTIC

IN-FLIGHT INVESTIGATION OF A ROTATING CYLINDER-BASED STRUCTURAL EXCITATION SYSTEM FOR FLUTTER TESTING

Lura Vernon Washington Jun. 1993 22 p See also A93-34074

(RTOP 505-63-50)

(NASA-TM-4512; H-1883; NAS 1.15:4512) Avail: CASI HC A03/MF A01

A research excitation system was test flown at the NASA Dryden Flight Research Facility on the two-seat F-16XL aircraft. The excitation system is a wingtip-mounted vane with a rotating slotted cylinder at the trailing edge. As the cylinder rotates during flight, the flow is alternately deflected upward and downward through the slot, resulting in a periodic lift force at twice the cylinder's rotational frequency. Flight testing was conducted to determine the excitation system's effectiveness in the subsonic, transonic, and supersonic flight regimes. Primary research objectives were to determine the system's ability to develop adequate force levels to excite the aircraft's structure and to determine the frequency range over which the system could excite structural modes of the aircraft. In addition, studies were conducted to determine optimal excitation parameters, such as sweep duration, sweep type, and energy levels. The results from the exciter were compared with results from atmospheric turbulence excitation at the same flight conditions. The comparison indicated that the vane with a rotating slotted cylinder provides superior results. The results from the forced excitation were of higher quality and had less variation than the results from atmospheric turbulence. The forced excitation data also invariably yielded higher structural damping values than those from the atmospheric turbulence data. Author

LIFT-FAN AIRCRAFT: LESSONS LEARNED-THE PILOT'S PERSPECTIVE

Ronald M. Gerdes Aug. 1993 33 p

(NASA Order A-24364-D)

(NASA-CR-177620; A-93114; NAS 1.26:177620) Avail: CASI HC A03/MF A01

This paper is written from an engineering test pilot's point of view. Its purpose is to present lift-fan 'lessons learned' from the perspective of first-hand experience accumulated during the period 1962 through 1988 while flight testing vertical/short take-off and landing (V/STOL) experimental aircraft and evaluating piloted engineering simulations of promising V/STOL concepts. Specifically, the scope of the discussions to follow is primarily based upon a critical review of the writer's personal accounts of 30 hours of XV-5A/B and 2 hours of X-14A flight testing as well as a limited simulator evaluation of the Grumman Design 755 lift-fan aircraft. Opinions of other test pilots who flew these aircraft and the aircraft simulator are also included and supplement the writer's comments. Furthermore, the lessons learned are presented from the perspective of the writer's flying experience: 10,000 hours in 100 fixed- and rotary-wing aircraft including 330 hours in 5 experimental V/STOL research aircraft. The paper is organized to present to the reader a clear picture of lift-fan lessons learned from three distinct points of view in order to facilitate application of the lesson principles to future designs. Lessons learned are first discussed with respect to case histories of specific flight and simulator investigations. These principles are then organized and restated with respect to four selected design criteria categories in Appendix I. Lastly, Appendix II is a discussion of the design of a hypothetical supersonic short take-off vertical landing (STOVL) fighter/attack aircraft. Author

ADAPTIVE ALGORITHM FOR AIRCRAFT CONFIGURATION IN TURBULENT FLOW Final Report, 10 Jan. 1991 - 30 Sep. 1992

John Kallinderis 25 Nov. 1992 57 p

(Grant AF-AFOSR-0022-91)

(AD-A266188; CAR-92-8; AFOSR-93-0433TR) Avail: CASI HC A04/MF A01

The flow around aircraft configurations has been simulated. A code for numerical simulation and study of 3-D aircraft flowfields has been developed. The code consists of a hybrid scheme which solves the Navier-Stokes equations within the viscous regions around the aircraft while the simple Euler system is solved everywhere else. Efficient resolution of local flow physics such as shear layers, shock waves, and vortices is achieved by a specially developed adaptive grid algorithm. The method employs division and/or deletion of grid cells, as well as redistribution of points in order to resolve local flow features more accurately and efficiently. A hybrid grid consisting of prisms and tetrahedra grid-cells is employed. The first type is appropriate for the viscous regions, while the second type is suitable for the inviscid regions. A grid generator of prisms around an F-16-type aircraft was developed. Flow visualization is greatly enhanced with a developed computer graphics code. DTIC

TRAJECTORY OPTIMIZATION FOR THE NATIONAL AEROSPACE PLANE Final Report, 13 Jun. 1992 - 30 Oct. 1993

Ping Lu Nov. 1993 28 p

(Grant NAG1-1255)

(NASA-CR-194618; NAS 1.26:194618) Avail: CASI HC A03/MF A01

The objective of this second phase research is to investigate the optimal ascent trajectory for the National Aerospace Plane (NASP) from runway take-off to orbital insertion and address the unique problems associated with the hypersonic flight trajectory optimization. The trajectory optimization problem for an aerospace plane is a highly challenging problem because of the complexity involved. Previous work has been successful in obtaining sub-optimal trajectories by using energy-state approximation and time-scale decomposition techniques. But it is known that the energy-state approximation is not valid in certain portions of the trajectory. This research aims at employing full dynamics of the aerospace plane and emphasizing direct trajectory optimization methods. The major accomplishments of this research include the first-time development of an inverse dynamics approach in trajectory optimization which enables us to generate optimal trajectories for the aerospace plane efficiently and reliably, and general analytical solutions to constrained hypersonic trajectories that has wide application in trajectory optimization as well as in guidance and flight dynamics. Optimal trajectories in abort landing and ascent augmented with rocket propulsion and thrust vectoring control were also investigated. Motivated by this study, a new global trajectory optimization tool using continuous simulated annealing and a nonlinear predictive feedback guidance law have been under investigation and some promising results have been obtained, which may well lead to more significant development and application in the near future. AEROTHERMOELASTIC ANALYSIS OF A NASP DEMONSTRATOR MODEL

Jennifer Heeg, Thomas A. Zeiler (Lockheed Engineering and Sciences Co., Hampton, VA.), Anthony S. Pototzky (Lockheed Engineering and Sciences Co., Hampton, VA.), Charles V. Spain (Lockheed Engineering and Sciences Co., Hampton, VA.), and Walter C. Engelund Oct. 1993 13 p See also A93-33933

(RTOP 505-63-50-15)

(NASA-TM-109007; NAS 1.15:109007) Avail: CASI HC A03/MF A01

The proposed National Aerospace Plane (NASP) is designed to travel at speeds up to Mach 25. Because aerodynamic heating during high-speed flight through the atmosphere could destiffen a structure, significant couplings between the elastic and rigid body modes could result in lower flutter speeds and more pronounced aeroelastic response characteristics. These speeds will also generate thermal loads on the structure. The purpose of this research is to develop methodologies applicable to the NASP and to apply them to a representative model to determine its aerothermoelastic characteristics when subjected to these thermal loads. This paper describes an aerothermoelastic analysis of the generic hypersonic vehicle configuration. The steps involved in this analysis were: generating vehicle surface temperatures at the appropriate flight conditions; applying these temperatures to the vehicle's structure to predict changes in the stiffness resulting from material property degradation; predicting the vibration characteristics of the heated structure at the various temperature conditions; performing aerodynamic analyses; and conducting flutter analysis of the heated vehicle. Results of these analyses and conclusions representative of a NASP vehicle are provided in this paper. Author

DEFINITIONS OF TERMS RELATING TO AIRCRAFT WINDSCREENS, CANOPIES, AND TRANSPARENCIES Final Report, Oct. 1990 - Nov. 1992
Maryann H. Barbato, William N. Kama, Harry L. Task, Martha A. Hausmann, and John C. Bridenbaugh Mar. 1993 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-89-C-0532)
(AD-A268403; AL-TR-1993-0036) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents a glossary of terms relating to aircraft windscreens, canopies, and transparencies. It addresses the need to have a single reference source which provides a common vocabulary for use by designers, materials engineers, manufacturers, evaluators, maintenance personnel, and user agencies concerned with aircraft transparencies. Its intent is to facilitate and enhance communication between these disciplines by clarifying and defining terms used within the aircraft transparency industry. DTIC

EQUATIONS OF MOTION OF A HINGED BODY OVER A SPHERICAL EARTH Final Report, May 1990 - 1992
Megaera C. Halter Aug. 1993 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268408; NAWCWPNS-TP-8134) Avail: CASI HC A03

The six-degree-of-freedom (6-DOF) equations of motion are derived in vector form for a hinged vehicle flying over a spherical Earth. Initially, the most general form of the equations is developed assuming that the combustor may roll with respect to the body, as well as deflect in pitch and yaw. Next, the primary case is developed in which the combustor cannot roll with respect to the body. Finally, these equations are specialized to dime simpler cases. The motivation for deriving this set of equations is to support feasibility studies of the low drag ramjet (LDR), which is streamlined by deleting all aerodynamic surfaces. AH directional control comes from thrust vectoring, which is accomplished by deflecting the entire motor rather than just the exhaust nozzle, as in more conventional designs. Since the motor is a large fraction of the total vehicle mass, its inertia has a significant effect on the dynamics of the overall vehicle. Sufficient detail is included to serve as a tutorial. DTIC

NAVAL AVIATION: THE NAVY IS TAKING ACTIONS TO IMPROVE THE COMBAT CAPABILITIES OF ITS TACTICAL AIRCRAFT. REPORT TO CONGRESSIONAL REQUESTERS
Jul. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268002; GAO/NSIAD-93-204) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Chairman of the Legislation and National Security Subcommittee of the House Committee on Government Operations and the Chairman of the Oversight of Government Management Subcommittee of the Senate Committee on Governmental Affairs asked the General Accounting Office to determine whether certain aircraft had the capabilities needed to perform their assigned missions during Operation Desert Storm. This report focuses on several Navy and Marine Corps aircraft. Several factors contributed to the Gulf War victory by creating favorable conditions under which to plan and fight the war, and these should be considered when assessing the effectiveness of U.S. weapons in the war. Commanders had nearly 6 months to plan and develop an air campaign that when initiated, quickly gained air superiority and effectively neutralized much of Iraq's air defense system. In addition, Iraq's forces remained in a primarily defensive posture throughout the war. These factors helped enable the Coalition to determine its tactics and decide when and where offensive air and ground actions would occur. DTIC

TURBINE BLADE TIP FILM COOLING MEASUREMENTS M.S. Thesis
Dean A. Ward Dec. 1992 186 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267686; AFIT/CI/CIA-93-011) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In the design of gas turbine engines, the need to accurately know the heat transfer characteristics of the turbine blade tip is of extreme importance.

The pressure differential between the pressure and suction side of the blade induces a strong secondary flow of hot combustion gases through the clearance gap between the turbine blade tip and shroud. This leakage flow is detrimental to the tip of the blade. In order to minimize this leakage flow, designers need to accurately know the heat transfer characteristics of the blade and blade tip so that dimensional changes may be accurately predicted. If dimensional changes are accurately known, the clearance gap and the secondary flow may be minimized and the overall thermal efficiency of the gas turbine engine increased. In addition, increased blade life is often achieved by cooling of the blade and blade tip. DTIC

Personnel at the NASA Langley Research Center (NASA-Langley) and the NASA Dryden Flight Research Facility (NASA-Dryden) recently completed a joint acoustic flight test program. Several types of aircraft with high nozzle pressure ratio engines were flown to satisfy a twofold objective. First, assessments were made of subsonic climb-to-cruise noise from flights conducted at varying altitudes in a Mach 0.30 to 0.90 range. Second, using data from flights conducted at constant altitude in a Mach 0.30 to 0.95 range, engineers obtained a high quality noise database. This database was desired to validate the Aircraft Noise Prediction Program and other system noise prediction codes. NASA-Dryden personnel analyzed the engine data from several aircraft that were flown in the test program to determine the exhaust characteristics. The analysis of the exhaust characteristics from the F-18 aircraft are reported. An overview of the flight test planning, instrumentation, test procedures, data analysis, engine modeling codes, and results are presented. Author (revised)

ROTARY ENGINE PERFORMANCE COMPUTER PROGRAM (RCEMAP AND RCEMAPPC): USER'S GUIDE Final Report

Timothy A. Bartrand and Edward A. Willis Oct. 1993 240 p

(Contract NAS3-25266; RTOP 505-62-11)

(NASA-CR-191192; E-8133; NAS 1.26:191192) Avail: CASI HC A11/MF A03

This report is a user's guide for a computer code that simulates the performance of several rotary combustion engine configurations. It is intended to assist prospective users in getting started with RCEMAP and/or RCEMAPPC. RCEMAP (Rotary Combustion Engine performance MAP generating code) is the mainframe version, while RCEMAPPC is a simplified subset designed for the personal computer, or PC, environment. Both versions are based on an open, zero-dimensional combustion system model for the prediction of instantaneous pressures, temperature, chemical composition and other in-chamber thermodynamic properties. Both versions predict overall engine performance and thermal characteristics, including bmep, bsfc, exhaust gas temperature, average material temperatures, and turbocharger operating conditions. Required inputs include engine geometry, materials, constants for use in the combustion heat release model, and turbomachinery maps. Illustrative examples and sample input files for both versions are included. Author (revised)

EFFECT OF WIND TUNNEL ACOUSTIC MODES ON LINEAR OSCILLATING CASCADE AERODYNAMICS

Daniel H. Buffum and Sanford Fleeter (Purdue Univ., West Lafayette, IN.) May 1993 43 p Presented at the 38th ASME International Gas Turbine and Aeroengine Congress and Exposition, Cincinnati, OH, 24-27 May 1993; sponsored by ASME

(RTOP 505-62-10)

(NASA-TM-106367; E-8171; NAS 1.15:106367) Avail: CASI HC A03/MF A01

The aerodynamics of a biconvex airfoil cascade oscillating in torsion is investigated using the unsteady aerodynamic influence coefficient technique. For subsonic flow and reduced frequencies as large as 0.9, airfoil surface unsteady pressures resulting from oscillation of one of the airfoils are measured using flush-mounted high-frequency-response pressure transducers. The influence coefficient data are examined in detail and then used to predict the unsteady aerodynamics of a cascade oscillating at various interblade phase angles. These results are correlated with experimental data obtained in the traveling-wave mode of oscillation and linearized analysis predictions. It is found that the unsteady pressure disturbances created by an oscillating airfoil excite wind tunnel acoustic modes which have detrimental effects on the experimental data. Acoustic treatment is proposed to rectify this problem. Author

EFFECTS OF RVP, T(50), AND OXYGENATES ON HOT-START AND DRIVEABILITY PERFORMANCE AT HIGH AND LOW ALTITUDE

May 1993 99 p

(AD-A266382; CRC-584) Avail: CASI HC A05/MF A02

A two-phase test program was conducted during July and August 1992 in Longmont, Colorado, and Phoenix, Arizona. The program was designed to investigate the effects of Reid vapor pressure, T(50), and oxygenates on hot-start and driveability performance of vehicles operated at high and low altitude in high and intermediate ambient temperature ranges. The temperature ranges had means of 70 F and 84 F in Longmont and 99 F in Phoenix. Twenty 1983 - 1992 model-year vehicles were tested on a set of eighteen fuels which included six hydrocarbon only fuels, six gasoline ethanol blends, and six gasoline-MTBE blends. Fuel-injected vehicles produced only about one-third the demerits of the carbureted vehicles and were insensitive, in most cases, to T(50) and the other fuel variables studied. For carbureted vehicles, decreasing T(50) had no effect with high-RVP fuels, but reduced T(50) fuels degraded driveability with low-RVP fuels. In carbureted vehicles, gasoline oxygenate blends showed generally improved driveability at high altitude with high-RVP fuels. An alternative driveability procedure that emphasized stop-and-go driving showed no significant fuel effects. DTIC

(NASA-TM-4481; E-7651; NAS 1.15:4481; AVSCOM-TR-91-C-052) Avail: CASI HC A03/MF A01

An experimental and computational investigation of the NASA Lewis

Research Center's low-speed centrifugal compressor (LSCC) flow field was conducted using laser anemometry and Dawes' three-dimensional viscous code. The experimental configuration consisted of a backswept impeller followed by a vaneless diffuser. Measurements of the three-dimensional velocity field were acquired at several measurement planes through the compressor. The measurements describe both the throughflow and secondary velocity field along each measurement plane. In several cases the measurements provide details of the flow within the blade boundary layers. Insight into the complex flow physics within centrifugal compressors is provided by the computational fluid dynamics analysis (CFD), and assessment of the CFD predictions is provided by comparison with the measurements. Five-hole probe and hot-wire surveys at the inlet and exit to the impeller as well as surface flow visualization along the impeller blade surfaces provided independent confirmation of the laser measurement technique. The results clearly document the development of the throughflow velocity wake that is characteristic of unshrouded centrifugal compressors. Derived from text

JET ENGINE PERFORMANCE ENHANCEMENT THROUGH USE OF A WAVE-ROTOR TOPPING CYCLE
Jack Wilson (Sverdrup Technology, Inc., Brook Park, OH.) and Daniel E. Paxson Washington Oct. 1993 12 p
(RTOP 505-62-10)
(NASA-TM-4486; E-7836; NAS 1.15:4486) Avail: CASI HC A03/MF A01

A simple model is used to calculate the thermal efficiency and specific power of simple jet engines and jet engines with a wave-rotor topping cycle. The performance of the wave rotor is based on measurements from a previous experiment. Applied to the case of an aircraft flying at Mach 0.8, the calculations show that an engine with a wave rotor topping cycle may have gains in thermal efficiency of approximately 1 to 2 percent and gains in specific power of approximately 10 to 16 percent over a simple jet engine with the same overall compression ratio. Even greater gains are possible if the wave rotor's performance can be improved. Author

(NASA-CR-194106; NAS 1.26:194106) Avail: CASI HC A03/MF A01

The research during the second reporting period has focused on robust control design for hypersonic vehicles. An already existing design for the Hypersonic Winged-Cone Configuration has been enhanced. Uncertainty models for the effects of propulsion system perturbations due to angle of attack variations, structural vibrations, and uncertainty in control effectiveness were developed. Using H(sub infinity) and mu-synthesis techniques, various control designs were performed in order to investigate the impact of these effects on achievable robust performance. Derived from text

In this report, we provide some examples of French, Russian, Chinese, and Japanese launch vehicles that have utilized fins in their designs. Next, the aerodynamic design of the fins is considered in Section 3. Some comments on basic static stability and control theory are followed by a brief description of an aerodynamic characteristics prediction code that was used to estimate the characteristics of a modified NLS 1.5 Stage vehicle. Alternative fin designs are proposed and some estimated aerodynamic characteristics presented and discussed. Also included in Section 3 is a discussion of possible methods of enhancement of the aerodynamic efficiency of fins, such as vortex generators and jet flaps. We consider the construction of fins for launch vehicles in Section 4 and offer an assessment of the state-of-the-art in the use of composites for aerodynamic control surfaces on high speed vehicles. We also comment on the use of smart materials for launch vehicle fins. The dynamic stability and control of a launch vehicle that utilizes both thrust vector control (engine nozzle gimballing) and movable fins is the subject addressed in Section 5. We give a short derivation of equations of motion for a launch vehicle moving in a vertical plane above a spherical earth, discuss the use of a gravity-turn nominal trajectory, and give the form of the period equations linearized about such a nominal. We then consider feedback control of vehicle attitude using both engine gimballing and fin deflection. Conclusions are stated and recommendations made in Section 6. An appendix contains aerodynamic data in tabular and graphical formats. Author (revised)

DEVELOPMENT OF AN AIR-TO-AIR REFUELING AUTOMATIC FLIGHT CONTROL SYSTEM USING QUANTITATIVE FEEDBACK THEORY M.S. Thesis
Dennis W. Trosen Jun. 1993 127 p
(AD-A266718; AFIT/GE/ENG/93J-03) Avail: CASI HC A07/MF A02

Quantitative Feedback Theory and the improved method Quantitative Feedback Theory are enhanced to include the rejection of disturbance at the system output. The enhanced Quantitative Feedback Theory and improved method Quantitative Feedback Theory processes are applied to the design of an automatic flight control system to regulate position of the C-135B fuel receiving aircraft relative to the tanker during air-to-air refueling. A simple feedback control system is developed that will achieve stable position regulation. State-space aircraft models are generated. An inner loop autopilot is designed to reduce the plant cutoff frequency and provide the system inputs for the Quantitative Feedback Theory compensators. Disturbance models representing disturbance due to wind gusts and refueling are developed. The flight control system is designed using the enhanced Quantitative Feedback Theory equations. Linear simulations are performed on MATRIX, and nonlinear simulations are run on EASY5x. The results of the simulations show excellent results. The simulation results indicate that air-to-air automatic flight control system are technically achievable, and that implementation in USAF aircraft is possible. DTIC

FIDELITY ASSESSMENT OF A UH-60A SIMULATION ON THE NASA AMES VERTICAL MOTION SIMULATOR
Adolph Atencio, Jr. Sep. 1993 318 p Sponsored by NASA, Washington
(RTOP 505-59-52)
(NASA-TM-104016; A-93071; NAS 1.15:104016; USAATC-TR-93-A-005) Avail: CASI HC A14/MF A03

Helicopter handling qualities research requires that a ground-based simulation be a high-fidelity representation of the actual helicopter, especially over the frequency range of the investigation. This experiment was performed to assess the current capability to simulate the UH-60A Black Hawk helicopter on the Vertical Motion Simulator (VMS) at NASA Ames, to develop a methodology for assessing the fidelity of a simulation, and to find the causes for lack of fidelity. The approach used was to compare the simulation to the flight vehicle for a series of tasks performed in flight and in the simulator. The results show that subjective handling qualities ratings from flight to simulator overlap, and the mathematical model matches the UH-60A helicopter very well over the range of frequencies critical to handling qualities evaluation. Pilot comments, however, indicate a need for improvement in the perceptual fidelity of the simulation in the areas of motion and visual cuing. The methodology used to make the fidelity assessment proved useful in showing differences in pilot work load and strategy, but additional work is needed to refine objective methods for determining causes of lack of fidelity. AERODYNAMIC/DYNAMIC/CONTROL INTERACTION Final Report, 15 Oct. 1989 - 14 Oct. 1992

Dean T. Mook and Ali H. Nayfeh 22 Dec. 1992 22 p

(Grant AF-AFOSR-0032-90)

(AD-A266187; AFOSR-93-0443TR) Avail: CASI HC A03/MF A01

The present report attempts to present a comprehensive review of achievements made under the support of a continuing series of related AFOSR grants. The essence of all the work was to develop numerical simulations that capture the interactions among aerodynamics, rigid-body dynamics, structural dynamics, and control systems. All of these components of a flying airplane were viewed simply as elements of a single dynamic system. All the work led toward an end result in which a maneuvering aircraft could be simulated without resorting to wind-tunnel or flight tests. A major obstacle to this development is the fact that one must know the motion of the aircraft and its control-surface deflections in order to calculate the flowfield, and one must know the flowfield in order to calculate the aerodynamic forces and, from them, the motions. One cannot determine the flowfield unless one knows the motion of the airplane and one cannot determine the motion unless one knows the flowfield. In this work the PI's have made significant advances in the development of the needed methodology. By expanding the structural deflections in terms of the free-vibration modes, the principal investigators were able to covert the governing partial-differential equations of the structure into a system of ordinary-differential equations. The aerodynamic loads were obtained by refining and extending the vortex-lattice concept. However, it must be noted that both the aerodynamic model and the structural models used in the examples can be changed, by simply changing subroutines in the general code, without changing the general approach. A COMPARATIVE STUDY OF ANALOG AND DIGITAL CONTROL LAWS FOR THE UMCSL TRUSS M.S. Thesis

Anthony M. Mitchell 1992 157 p

(AD-A267980; AFIT/CI/CIA-93-008) Avail: CASI HC A08/MF A02

This thesis is based on research conducted at the University of Washington Department of Aeronautics and Astronautics Control Systems Laboratory (UWCSL). The UWCSL 20-bay planar truss is a replica of an experimental testbed at the United States Air Force Academy. Validation and modification of existing finite element models of the truss and the two primary means of structurally-borne actuation, the air jet thrusters and the reaction mass actuators, was accomplished and is discussed. Verification of classical analog controllers to actively suppress vibration of the planar bending modes of the truss using the air jet thruster and reaction mass actuators in independent and in hybrid configurations is reported in this thesis. The discretization and digitization of the classical control law was accomplished and the results of computer simulation, linear and non-linear, and experimental testing are reported. A comparison of the performance of the analog and the digital control laws is reported. The design of an optimal controller for the reaction mass actuators utilizing Linear Quadratic (LQ) techniques is reported, and includes non-linear simulation. Simulation of hybrid actuation utilizing the optimal reaction mass actuator control law and the classical air jet thruster controllers is also reported. Recommendations for future study based upon both the hardware implementation and the computer simulation are suggested in the conclusions of this thesis. DTIC

VIBRO-ACOUSTIC ANALYSIS OF AN AIRCRAFT MAINTENANCE DOCK Final Report

James Wilcoski and Louis Sutherland Aug. 1992 253 p

(Contract MIPR-ENM9486)

(AD-A266778; CERL-TR-FM-92/03) Avail: CASI HC A12/MF A03

This report documents an analysis of the effects of high-level acoustic environments on an Aircraft Maintenance Dock (AMD) designed for the U.S. Air Force by the U.S. Army Corps of Engineers. The analysis includes detailed estimation of the maximum sound levels inside the facility, identification of facility components that are potentially sensitive to high-level vibro-acoustic loads, and a summary of design considerations appropriate for this environment. Several critical components of the AMD were analyzed. Design modifications have been recommended as a result of this analysis for this facility, including increases in ductwork thickness, a new ductwork joint design, and vibration isolation for ductwork, exhaust fans, pipe systems, light fixtures, and wind truss supports. A summary of recommended design practices to minimize potential structural damage or equipment malfunction due to the high vibro-acoustic environments was developed. The type of steel construction to be employed for this facility is not normally exposed to high-intensity vibro-acoustic loading. However, if proper consideration is given to the vibro-acoustic loads specified here for building design and qualifications of internal equipment, the planned use of the facility should not be significantly impaired. DEVELOPMENT OF A QUIET SUPERSONIC WIND TUNNEL WITH A CRYOGENIC ADAPTIVE NOZZLE Progress Report

Stephen W. D. Wolf Oct. 1993 138 p Original contains color illustrations

(Contract NCC2-604)

(NASA-CR-194548; NAS 1.26:194548; MCAT-93-19) Avail: CASI HC A07/MF A02; 6 functional color pages

The main objective of this work is to develop an interim Quiet (low-disturbance) supersonic wind tunnel for the NASA-Ames Fluid Mechanics Laboratory (FML). The main emphasis is to bring on-line a full-scale Mach 1.6 tunnel as rapidly as possible to impact the NASA High Speed Research Program (HSRP). The development of a cryogenic adaptive nozzle and other sophisticated features of the tunnel will now happen later, after the full scale wind tunnel is in operation. The work under this contract for the period of this report can be summarized as follows: provide aerodynamic design requirements for the NASA-Ames Fluid Mechanics Laboratory (FML) Laminar Flow Supersonic Wind Tunnel (LFSWT); research design parameters for a unique Mach 1.6 drive system for the LFSWT using an 1/8th-scale Proof-of-Concept (PoC) supersonic wind tunnel; carry out boundary layer transition studies in PoC to aid the design of critical components of the LFSWT; appraise the State of the Art in quiet supersonic wind tunnel design; and help develop a supersonic research capability within the FML particularly in the areas of high speed transition measurements and schlieren techniques. The body of this annual report summarizes the work of the Principal Investigator. Derived from text

WALL INTERFERENCE AND BOUNDARY SIMULATION IN A TRANSONIC WIND TUNNEL WITH A DISCRETELY SLOTTED TEST SECTION
Jassim A. Al-Saadi Washington Sep. 1993 75 p
(RTOP 505-59-54-01)
(NASA-TP-3334; L-16973; NAS 1.60:3334) Avail: CASI HC A04/MF A01

A computational simulation of a transonic wind tunnel test section with longitudinally slotted walls is developed and described herein. The nonlinear slot model includes dynamic pressure effects and a plenum pressure constraint, and each slot is treated individually. The solution is performed using a finite-difference method that solves an extended transonic small disturbance equation. The walls serve as the outer boundary conditions in the relaxation technique, and an interaction procedure is used at the slotted walls. Measured boundary pressures are not required to establish the wall conditions but are currently used to assess the accuracy of the simulation. This method can also calculate a free-air solution as well as solutions that employ the classical homogeneous wall conditions. The simulation is used to examine two commercial transport aircraft models at a supercritical Mach number for zero-lift and cruise conditions. Good agreement between measured and calculated wall pressures is obtained for the model geometries and flow conditions examined herein. Some localized disagreement is noted, which is attributed to improper simulation of viscous effects in the slots. Author

(AD-A267170; ARL-TN-17; DODA-AR-006-680) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The standby flight instruments are replicated on two high resolution raster displays for the F/A-18 research simulator. A software package was developed using NOVA*CG1, an implementation of the CGI graphics standard, to control a MVME393 multi-channel graphics controller. The software is written in C for the Motorola MVME147 single board computer under the UNIX System V/68 operating system. Increased performance is achieved by decomposing the instrument dial pointers into a number of trapezoids, and storing these as device level command lists. DTIC

DESIGN OF NON-SLED SETUP TO MEASURE HEAD INJURY CRITERIA
Hamid M. Lankarani and Sanjeev Aravinthan 1993 117 p
(NIAR-92-20) Avail: CASI HC A06/MF A02

Injury assessment measurements for important body regions are critical issues in the evaluation of occupant protection systems. In this project a new method is designed and developed to evaluate the head injury criteria. Various methods are prevalent in analyzing a head injury. However, these methods are found to be more complex, time consuming, and expensive. A typical method is the 'sled test' which is followed universally to mimic occupant kinematics in frontal crash. In this study, three methods of 'non-sled' test setup were designed to measure head injury criteria in a more simple, reliable, and cost-effective way. In addition to the above, we firmly believe these methods are more versatile and can deliver more accurate results. Author (revised)

THEORETICAL IMPLICATIONS AND EMPIRICAL FINDINGS ON INSTRUCTIONAL CONTROL AND PART-WHOLE-TASK TRAINING Final Report, Jan. 1992 - Apr. 1993
Joseph S. Mattoon and Bernell J. Edwards Jun. 1993 35 p
(AF Proj. 1123)
(AD-A267826; AL/HR-TR-1993-0089) Avail: CASI HC A03/MF A01

A review of the literature and two experiments were conducted to examine instructional control and part-whole-task training methods applied to simulation training. The literature and results of the experiments indicate that learner-controlled systems are probably less effective than those that use computer programming to automatically adjust instructional support according to the learners' progress during practice activities Also, part-task training methods may facilitate the effectiveness of instructional control by reducing the complexity of performance measures and en route learning tasks. An overview is presented of a conceptual study of a lunar revolving satellite whose missions are to conduct the following: topographical, geological, and crust explorations of the moon; water resource explorations at lunar polar region; and a lunar surface landing experiment. The study was conducted for two cases: a two ton observation satellite and an observation satellite plus landing experiment vehicle. It was concluded that transfer to a development phase was feasible in both cases. The topics covered include the following: mission study; mission analysis, system study, and analysis of lunar revolving observation satellite; subsystem study of lunar revolving observation satellite; study, analysis, and subsystem study of landing experiment system; and study of the development program.

The European Retrievable Carrier (Eureca) is the first platform designed to be retrieved from orbit and possibly to be relaunched with a different payload. For its first mission in July 1992, Eureca was deployed from the Space Shuttle Atlantis (flight STS 46) by ESA astronaut and mission specialist, Claude Nicollier. It then used its own propulsion system to transfer to its operational orbit at 508 km where, after commissioning, payload operation started. Since Eureca has been specially designed for investigations in the microgravity environment, this publication concentrates mainly on this aspect of the mission. Microgravity research is a newcomer to the scientific disciplines and is perhaps not very well known to, or understood by, those not directly involved. An explanation of the microgravity environment is presented. This is followed by an explanation of the interest microgravity holds for researchers, and a review of the different scientific fields, Material Sciences, Fluid Physics, Life Sciences, for which investigations have been carried out during the Eureca mission, together with a brief description of the on-board facilities and their flight performances. The last two chapters describe the Space Science and technology experiments carried out during the mission. Derived from text

MILITARY SPACE PROGRAMS IN THE PRESS: AN ANALYSIS FOR CHANGE M.S. Thesis
John Kennedy 1993 79 p
(AD-A267799) Avail: CASI HC A05/MF A01

The military space program is not known in any great detail by the general American public. The reasons for this lie in the heavily classified nature of the majority of military space programs. This, in turn, brings the media into conflict with the military. It is a conflict derived from the media's desire to have freedom of access to information vs. national security requirements. DTIC

NEIGHBORING EXTREMAL GUIDANCE FOR SYSTEMS WITH PIECEWISE LINEAR CONTROL USING TIME AS THE REFERENCE VARIABLE M.S. Thesis
William A. Libby May 1993 58 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267942; AFIT/CI/CIA-93-113) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A guidance law for the control of a system in the neighborhood of a nominal suboptimal trajectory is developed. The guidance law is demonstrated using a lunar launch problem with constraints at orbit entry. A set of precomputed gains is used by the guidance law to operate on an extremal path in the neighborhood of the suboptimal trajectory. The guidance law and gains are designed to minimize the change in the desired performance index while still satisfying the final path constraints. In the lunar launch problem, the nominal suboptimal trajectory minimizes the final time using piecewise linear control. This trajectory is obtained to provide a nominal control history. The guidance law is found by minimizing the second variation of the suboptimal trajectory performance index subject to the final constraints being satisfied. For the lunar launch problem, the guidance law leads to a set of gains that relates deviations from the suboptimal trajectory to required changes in the nominal control history. The deviations from the suboptimal trajectory, used together with the precomputed gains, determines the change in the nominal control history required to meet the final constraints while minimizing the change in the final time. TEST PLAN FOR THE EVALUATION OF THE INITIAL CAPABILITY OF THE NATIONAL SATELLITE TEST BED: PHASE 1D Final Report
Daniel G. OLaughlin Aug. 1993 48 p
(Contract DTFA01-93-C-00001)
(DOT/FAA/RD-93/20; MTR-93W0000075) Avail: CASI HC A03/MF A01

This document contains a plan for testing Wide-area Differential GPS (WDGPS) and Wide-area Integrity Broadcast (Wig) concepts in the National Satellite Test Bed (NSTB). This report documents the test plan for the next test subphase (ID), and covers the flight test definition, data collection, reduction and analysis, organizational responsibilities, and schedule. The specific objectives of the testing during this subphase are to: obtain data on the time to detect, transmit, process, and receive an integrity alarm using a satellite broadcast relay of the alarm from the ground to the test aircraft; obtain preliminary data on the performance of WDGPS, and specifically of ionospheric corrections for WDGPS using a satellite broadcast of the differential corrections; and compare the performance achieved with WDGPS with that of Local-Area Differential GPS (LDGPS). DESIGN OF AN EXPERIMENT HARDWARE FOR THE ESA SPACE FACILITY BIOPAN Thesis - Fachhochschule Aachen [DAS DESIGN EINER FLUGHARDWARE FUR EIN WELTRAUMEXPERIMENT AUF DER ESA-EINRICHTUNG BIOPAN]
Rene Delonge Dec. 1992 106 p In GERMAN
(DLR-FB-93-06; ETN-93-94621) Avail: CASI HC A06/MF A02

The design of sample carriers, for an experiment concerning the exposure of biological systems to the space environment, which will be part of the multiuser experiment facility called BIOPAN (Biological Pan), is described. BIOPAN is a circular, pan shaped container, which will be mounted on the sphere shaped descent module of the BION satellite assembly. The lid of this container will be opened after attaining the proper orbit to expose all accommodated experiments. The single sample carriers described are of a regular hexagonal shape and were designed in respect to the available area on the experiment platform of the container. A quartz disc on top and a circular membrane inside with corresponding horizontal and vertical air shafts ensure the exposure to the characteristic space environment. ESA

NUMERICAL MODELING OF THE TEMPERATURE GRADIENTS AND SPECTRA OF THE PLASMA ARMATURE ON THUNDERBOLT
Memorandum Report
Paul C. Kepple and Robert W. Clark 14 Jun. 1993 42 p (AD-A266414; NRL/MR/6721-93-7317) Avail: CASI HC A03/MF A01
Numerical simulations of the spectra recorded on Thunderbolt shots 26 and 27 are presented. The calculations proceed via multifrequency radiation transport and are based on the assumptions that the plasma armature is cylindrically symmetric, the atomic constituents are homogeneously mixed and in pressure equilibrium, and the temperature gradient is specified. For the case of shot 27, the simulation is in excellent agreement with experiment and leads to a specific inference of a temperature gradient. For the case of shot 26, (where one capacitor bank fired early) the simulations indicate that the plasma armature for this shot did not satisfy some or all of the assumptions above. Since the aluminum absorption feature on shot 26 is too narrow relative to the B 2 and Cu 1 features there probably was a 'blob' of aluminum near the wall. DTIC

VERTICAL-TAIL AERODYNAMIC CONFIGURATION OF SPACE SHUTTLE ORBITER
Zhu Yikun 16 Jul. 1993 23 p Transl. into ENGLISH from unidentified Chinese language periodical, p 115-123
(AD-A267723; FASTC-ID(RS)T-0731-92) Avail: CASI HC A03/MF A01

From a discussion of the principle of the vertical-tail aerodynamic configuration of the Space Shuttle Orbiter in the preliminary design stage and analysis of the vertical-tail aerodynamic configuration (including layout) of the present-day Space Shuttle Orbiter, the author clarified three possible modes of vertical-tail aerodynamic configuration of the Space Shuttle Orbiter. The principal measures for the lateral-direction aerodynamic characteristics for an improved Space Shuttle Orbiter are also clarified. These results have direct reference value on the aerodynamic configuration and the preliminary design on the exterior shape of the Space Shuttle Orbiter. DTIC

SERPENTINE MANIPULATOR PLANNING AND CONTROL FOR NASA SPACE-SHUTTLE PAYLOAD SERVICING
Herman Herman and Hagen Schempf Oct. 1992 37 p
(AD-A266961; CMU-RI-TR-92-10) Avail: CASI HC A03/MF A01

The use of a highly-redundant manipulator, so-called 'serpentine' manipulator, is proposed as a solution for servicing space-payloads during the payload installation process before launch on the Space-Shuttle. The staging of the system would be inside a large cleanroom area, the Payload Changeout Room (PCR), which sits on the Rotating Service Structure (RSS), allowing it to be swung into mated contact with the Space-Shuttle as it sits on the launchpad at the John F. Kennedy Space Center in Cape Canaveral, Florida. This report is not so much concerned with the design and implementation issues associated with a serpentine manipulator, but rather with the planning, control and user-interface issues. We thus present a brief introduction to the actual application environment and its restrictions, followed by the theoretical background and implementation issues of planning and control algorithms developed specifically for a serpentine manipulator operating within the confined spaces of the PCR and the Space-Shuttle cargo-bay. The approach used to generate a continuous path is to develop and use a minimizing continuous energy curve for the manipulator, and then fit the discretized link-sections to that curve. The operator is then able to modify this curve directly, allowing for shaping of the serpentine, and for the placement of obstacles that can then be avoided. This algorithm can be implemented in real-time, and curve-parameters can also be adjusted such as flexibility and curvature of the curve. An A* method is used to search for the shortest distance between two goal points in order to construct the curve. In order to avoid obstacles (real and artificial), available from a database or which can be placed by the operator using the operator interface display, we use an obstacle potential field FIRAS function. SPACE STATION THERMAL STORAGE/REFRIGERATION SYSTEM RESEARCH AND DEVELOPMENT Final Report
W. G. Dean and Z. S. Karu 26 Feb. 1993 345 p
(Contract NAS8-36401)
(NASA-CR-193841; NAS 1.26:193841; LMSC-HSV-TR-P037989) Avail: CASI HC A15/MF A03

Space Station thermal loading conditions represent an order of magnitude increase over current and previous spacecraft such as Skylab, Apollo, Pegasus III, Lunar Rover Vehicle, and Lockheed TRIDENT missiles. Thermal storage units (TSU's) were successfully used on these as well as many applications for ground based solar energy storage applications. It is desirable to store thermal energy during peak loading conditions as an alternative to providing increased radiator surface area which adds to the weight of the system. Basically, TSU's store heat by melting a phase change material (PCM) such as a paraffin. The physical property data for the PCM's used in the design of these TSU's is well defined in the literature. Design techniques are generally well established for the TSU's. However, the Space Station provides a new challenge in the application of these data and techniques because of three factors: the large size of the TSU required, the integration of the TSU for the Space Station thermal management concept with its diverse opportunities for storage application, and the TSU's interface with a two-phase (liquid/vapor) thermal bus/central heat rejection system. The objective in the thermal storage research and development task was to design, fabricate, and test a demonstration unit. One test article was to be a passive thermal storage unit capable of storing frozen food at -20 F for a minimum of 90 days. A second unit was to be capable of storing frozen biological samples at -94 F, again for a minimum of 90 days. The articles developed were compatible with shuttle mission conditions, including safety and handling by astronauts. Further, storage rack concepts were presented so that these units can be integrated into Space Station logistics module storage racks. The extreme sensitivity of spacecraft radiator systems design-to-heat rejection temperature requirements is well known. A large radiator area penalty is incurred if low temperatures are accommodated via a single centralized radiator system. As per the scope of work of this task, the applicability of refrigeration system tailored to meet the specialized requirements of storage of food and biological samples was investigated. The issues addressed were the anticipated power consumption and feasible designs and cycles for meeting specific storage requirements. Further, development issues were assessed related to the operation of vapor compression systems in micro-gravity addressing separation of vapor and liquid phases (via capillary systems). Author (revised)

The Shuttle Potential and Return Electron Experiment (SPREE) was flown as part of the Tethered Satellite System (TSS-1) on STS-46 launched on 31 Jul. 1992. A significant portion of this contract has been spent on the design and development of the SPREE analyzer system. The successful launch and operation of the SPREE during the TSS-1 and EOIM mission were the culmination of the past five years' work. This final report details the SPREE system as flown and some of the preliminary results. These successes include a real-time charging detection algorithm that correctly and accurately diagnosed the potential of the Shuttle with respect to the ambient plasma, a particle correlator system that was able to accurately detect and analyze wave/particle interactions triggered by electron beam operations, a pair of digital data recorders that archived 5 Gigabytes of data, two sets of triquadraspherical electrostatic analyzers that measured the flux of electrons and ions from 10 eV to 10 KeV and from 10000 to 1 x 10(exp 14) particles/sq cm-ster-sec., and occasional operating pressures that exceeded 0.0001 Torr. HUMAN TRANSPORTATION SYSTEM (HTS) STUDY, VOLUME 2 Final Report
N. Lance, M. S. Geyer, and M. T. Gaunce Oct. 1993 560 p
(RTOP 906-11-01-01)
(NASA-TM-104779-Vol-2; S-739; NAS 1.15:104779-Vol-2) Avail: CASI HC A24/MF A04

This report summarizes work completed under the Human Transportation System Study. This study was conducted by the New Initiatives Office at JSC with the technical support of Boeing, General Dynamics, Lockheed, McDonnell-Douglas, Martin Marietta, and Rockwell. The study was designed to generate information on determining the appropriate path to follow for new system development to meet the Nation's space transportation needs. The study evaluates 18 transportation architecture options using a parametric set of mission requirements. These options include use of current systems (e.g., Shuttle, Titan, etc.) as well as proposed systems (e.g., PLS, Single-Stage-to-Orbit, etc.) to assess the impact of various considerations, such as the cost of alternate access, or the benefit of separating people and cargo. The architecture options are compared to each other with six measurable evaluation criteria or attributes. They are: funding profile, human safety, probability of mission success, architecture cost risk, launch schedule confidence, and environmental impact. Values for these attributes are presented for the architecture options, with pertinent conclusions and recommendations. Derived from text

POSTFLIGHT HARDWARE EVALUATION 360T026 (RSRM-26, STS-47) Final Report
Greg Nielson May 1993 279 p
(Contract NAS8-38100)
(NASA-CR-192559; NAS 1.26:192559; TWR-64204) Avail: CASI HC A13/MF A03

The final report for the Clearfield disassembly evaluation and a continuation of the KSC postflight assessment for the 360T026 (STS-47) Redesigned Solid Rocket Motor (RSRM) flight set is provided. All observed hardware conditions were documented on PFOR's and are included in Appendices A, B, and C. Appendices D and E contain the measurements and safety factor data for the nozzle and insulation components. This report, along with the KSC Ten-Day Postflight Hardware Evaluation Report (TWR-64203), represents a summary of the 360T026 hardware evaluation. The as-flown hardware configuration is documented in TWR-60472. Disassembly evaluation photograph numbers are logged in TWA-1987. The 360T026 flight set disassembly evaluations described were performed at the RSRM Refurbishment Facility in Clearfield, Utah. The final factory joint

demate occurred on 12 April 1993. Detailed evaluations were performed in accordance with the Clearfield Postflight Engineering Evaluation Plan (PEEP), TWR-50051, Revision A. All observations were compared against limits that are also defined in the PEEP. These limits outline the criteria for categorizing the observations as acceptable, reportable, or critical. Hardware conditions that were unexpected and/or determined to be reportable or critical were evaluated by the applicable CPT and tracked through the PFAR system. Author (revised)

BANDWIDTH CHARACTERISTICS OF MULTIMEDIA DATA TRAFFIC ON A LOCAL AREA NETWORK
Shery L. Chuang, Sharon Doubek (RECOM Software, Inc., San Jose, CA.), and Richard F. Haines Sep. 1993 11 p
(RTOP 476-14-03)
(NASA-TM-104026; A-93088; NAS 1.15:104026) Avail: CASI HC A03/MF A01

Limited spacecraft communication links call for users to investigate the potential use of video compression and multimedia technologies to optimize bandwidth allocations. The objective was to determine the transmission characteristics of multimedia data - motion video, text or bitmap graphics, and files transmitted independently and simultaneously over an ethernet local area network. Commercial desktop video teleconferencing hardware and software and Intel's proprietary Digital Video Interactive (DVI) video compression algorithm were used, and typical task scenarios were selected. The transmission time, packet size, number of packets, and network utilization of the data were recorded. Each data type - compressed motion video, text and/or bitmapped graphics, and a compressed image file - was first transmitted independently and its characteristics recorded. The results showed that an average bandwidth of 7.4 kilobits per second (kbps) was used to transmit graphics; an average bandwidth of 86.8 kbps was used to transmit an 18.9-kilobyte (kB) image file; a bandwidth of 728.9 kbps was used to transmit compressed motion video at 15 frames per second (fps); and a bandwidth of 75.9 kbps was used to transmit compressed motion video at 1.5 fps. Average packet sizes were 933 bytes for graphics, 498.5 bytes for the image file, 345.8 bytes for motion video at 15 fps, and 341.9 bytes for motion video at 1.5 fps. Simultaneous transmission of multimedia data types was also characterized. The multimedia packets used transmission bandwidths of 341.4 kbps and 105.8kbps. Bandwidth utilization varied according to the frame rate (frames per second) setting for the transmission of motion video. Packet size did not vary significantly between the data types. When these characteristics are applied to Space Station Freedom (SSF), the packet sizes fall within the maximum specified by the Consultative Committee for Space Data Systems (CCSDS). The uplink of imagery to SSF may be performed at minimal frame rates and/or within seconds of delay, depending on the user's allocated bandwidth. Further research to identify the acceptable delay interval and its impact on human performance is required. Additional studies in network performance using various video compression algorithms and integrated multimedia techniques are needed to determine the optimal design approach for utilizing SSF's data communications system. EVALUATION OF MIDBAND ANALOG FIBER OPTIC TELEMETRY LINKS
G. J. Hansen May 1993 46 p
(Contract DE-AC04-76DP-00789)
(DE93-015128; SAND-93-0910) Avail: CASI HC A03/MF A01

Midband (1 KHz-500 MHz) analog fiber optic data links were purchased for evaluation from three suppliers. Ortel Corp., Alhambra, CA, provided units built to the specifications. Kaman Sciences Corp, Colorado Springs, CO, and Laser Diode Inc., Princeton, NJ, provided units similar to the specification but with significant differences. The final version of the Ortel units met the specification but were marginal in dynamic range. The other units failed to meet the specification but showed promise for future application. DOE

ON-BOARD B-ISDN FAST PACKET SWITCHING ARCHITECTURES. PHASE 1: STUDY Final Report
Faris Faris, Thomas Inukai, Fred Lee, Dilip Paul, and Dong-Jye Shyy Oct. 1993 499 p
(Contract NASw-4528; RTOP 506-72-21)
(NASA-CR-191143; E-8137; NAS 1.26:191143) Avail: CASI HC A21/MF A04

The broadband integrate services digital network (B-ISDN) is an emerging telecommunications technology that will meet most of the telecommunications networking needs in the mid-1990's to early next century. The satellite-based system is well positioned for providing B-ISDN service with its inherent capabilities of point-to-multipoint and broadcast transmission, virtually unlimited connectivity between any two points within a beam coverage, short deployment time of communications facility, flexible and dynamic reallocation of space segment capacity, and distance insensitive cost. On-board processing satellites, particularly in a multiple spot beam environment, will provide enhanced connectivity, better performance, optimized access and transmission link design, and lower user service cost. The following are described: the user and network aspects of broadband services; the current development status in broadband services; various satellite network architectures including system design issues; and various fast packet switch architectures and their detail designs. NASA LEWIS MESHED VSAT WORKSHOP MEETING SUMMARY
William Ivancic Nov. 1993 7 p Proposed for presentation at the 15th International Communications Satellite Conference, San Diego, CA, 28 Feb. - 3 Mar. 1994; sponsored by AIAA
(RTOP 506-72-21)
(NASA-TM-106332; E-8093; NAS 1.15:106332; AIAA Paper 94-0993)
Avail: CASI HC A02/MF A01

NASA Lewis Research Center's Space Electronics Division (SED) hosted a workshop to address specific topics related to future meshed very small-aperture terminal (VSAT) satellite communications networks. The ideas generated by this workshop will help to identify potential markets and focus technology development within the commercial satellite communications industry and NASA. The workshop resulted in recommendations concerning these principal points of interest: the window of opportunity for a meshed VSAT system; system availability; ground terminal antenna sizes; recommended multifrequency for time division multiple access (TDMA) uplink; a packet switch design concept for narrowband; and fault tolerance design concepts. This report presents a summary of group presentations and discussion associated with the technological, economic, and operational issues of meshed VSAT architectures that utilize processing satellites. ON-BOARD PACKET SWITCH ARCHITECTURES FOR COMMUNICATION SATELLITES
Mary Jo Shalkhauser and Jorge A. Quintana Sep. 1993 11 p
(RTOP 506-72-21)
(NASA-TM-106328; E-8087; NAS 1.15:106328) Avail: CASI HC A03/MF A01

NASA Lewis Research Center is developing an on-board information switching processor for a multichannel communications signal processing satellite. The information switching processor is a flexible, high-throughput, fault tolerant, on-board baseband packet switch used to route user data among user ground terminals. Through industry study contracts and in-house investigations, several packet switching architectures were examined for possible implementation. Three contention-free switching architectures were studied in detail, namely the shared memory approach, the shared bus approach, and the shared memory per beam approach. These three switching architectures are discussed and the advantages and disadvantages of each approach are examined. Author (revised)

RESULTS OF AN ELECTRICAL POWER SYSTEM FAULT STUDY (CDDF) Final Report No. N06
N. R. Dugal-Whitehead and Y. B. Johnson Washington Sep. 1993 44 p
(NASA-TP-3413; M-731; NAS 1.60:3413) Avail: CASI HC A03/MF A01

This report gives the results of an electrical power system fault study which has been conducted over the last 2 and one-half years. First, the results of the literature search into electrical power system faults in space and terrestrial power system applications are reported. A description of the intended implementations of the power system faults into the Large Autonomous Spacecraft Electrical Power System (LASEPS) breadboard is then presented. Then, the actual implementation of the faults into the breadboard is discussed along with a discussion describing the LASEPS breadboard. Finally, the results of the injected faults and breadboard failures are discussed. Author (revised)

SPACE COUNTERSURVEILLANCE: A REQUISITE FOR THEATER DEFENSE PLANNING Final Report
Donald A. Meyer 17 May 1993 37 p
(AD-A266871) Avail: CASI HC A03/MF A01

The first space war has been successfully fought hundreds of miles above the sands of the Middle East, and U.S. space warriors are now contemplating future conflicts and how space can better contribute to operational success on the battlefield. However, the lessons of U.S. space dominance during Desert Storm also received much attention from other nations -- many of which U.S. forces may someday face in a future skirmish. These nations have learned the value of space assets and are busily seeking to acquire a space surveillance capability of their own. The U.S. national military strategy calls for its forces to exercise space control and deny potential enemies use of the space medium when necessary -- but does the U.S. possess the weapons and plans to successfully accomplish this task? This paper examines both U.S. and enemy capabilities in the space warfare realm. Further, it suggests that the U.S. can better organize its space warfare personnel under a Space Component Commander concept to successfully accomplish the space countersurveillance mission at the theater level of operational warfare. PRELAUNCH OPTICAL CHARACTERIZATION OF THE LASER GEODYNAMIC SATELLITE (LAGEOS 2)
Peter O. Minott, Thomas W. Zagwodzki, Thomas Varghese (Allied-Signal Aerospace Co., Seabrook, MD.), and Michael Seldon (Allied-Signal Aerospace Co., Seabrook, MD.) Sep. 1993 343 p
(NASA-TP-3400; NAS 1.60:3400; Rept-93B00102) Avail: CASI HC A15/MF A03

The optical range correction (the distance between the apparent retroreflective skin of the satellite and the center of mass) of the LAGEOS 2 was determined using computer analysis of theoretical and experimentally measured far field diffraction patterns, and with short pulse lasers using both streak camera-based range receivers and more conventional PMT-based range receivers. The three measurement techniques yielded range correction values from 248 to 253 millimeters dependent on laser wavelength, pulsewidth, and polarization, location of the receiver in the far field diffraction pattern and detection technique (peak, half maximum, centroid, or constant fraction). The Lidar cross section of LAGEOS 2 was measured at 4 to 10 million square meters, comparable to the LAGEOS 1. Author

MINIMUM ACCOMMODATION FOR AEROBRAKE ASSEMBLY. PHASE 2: STRUCTURAL CONCEPTS FOR A LUNAR TRANSFER VEHICLE AEROBRAKE WHICH CAN BE ASSEMBLED ON ORBIT Final Report
John T. Dorsey, Judith J. Watson, and Robin D. Tutterow Oct. 1993 38 p
(RTOP 506-43-41-02)
(NASA-TM-107610; NAS 1.15:107610) Avail: CASI HC A03/MF A01

A multidisciplinary conceptual study was conducted to define a reusable lunar transfer vehicle (LTV) aerobrake which could be launched on a Space Shuttle of Titan 4 and assembled on orbit at Space Station Freedom. A major objective was to design an aerobrake, with integrated structure and thermal protection systems, which has a mass less than 20 percent (9040 lb) of the LTV lunar return mass. The aerobrake segmentation concepts, the structural concepts, a joint concept for assembly, and a structural design with analysis of the aerobrake are described. Results show that a 50-foot diameter LTV aerobrake can be designed for on-orbit assembly which will achieve the 20 percent mass budget.

ANALYSIS OF LEADING EDGE AND TRAILING EDGE COVER GLASS SAMPLES BEFORE AND AFTER TREATMENT WITH ADVANCED SATELLITE CONTAMINATION REMOVAL TECHNIQUES Report, Oct. 1991 - Jun. 1992
S. P. Hotaling Apr. 1993 38 p
(AD-A267055; RL-TR-93-51) Avail: CASI HC A03/MF A01

Two samples from LDEF experiment M0003-4 were analyzed for molecular and particulate contamination prior to and following treatment with advanced satellite contamination removal techniques (CO2 Gas/Solid Jet Spray and Oxygen Ion Beam). The pre- and post-cleaning measurements and analyses will be presented. The Jet Spray removed particulates in seconds. The low energy reactive oxygen ion beam removed 5000 A of photo-polymerized organic hydrocarbon contamination in less than 1 hour. Spectroscopic analytical techniques were applied to the analysis of cleaning efficiency including: Fourier Transform Infrared, Auger, X-ray Photoemission, Energy Dispersive X-ray, and Ultraviolet/Visible. The results of this work suggest that the contamination studied here was due to spacecraft self contamination enhanced by atomic oxygen plasma dynamics and solar UV radiation. These results also suggest the efficacy for the Jet Spray and Ion Beam contamination control technologies for spacecraft optical surfaces. DTIC

SATELLITE SITUATION REPORT, VOLUME 33, NO. 3
30 Sep. 1993 100 p
(NASA-TM-109278; NAS 1.15:109278) Avail: CASI HC A05/MF A02

This report consists of data computed at the U.S. Space Command, GSFC, or provided by satellite owners. A space objects box score table is presented with data under the following headings: source/organization, objects in orbit, and decayed objects. The objects in orbit and decayed objects headings have payload, debris, and total as subheadings. The bulk of the document is objects-in-orbit tables with data under the following headings: international designation, name, catalog number, source, launch date, period minutes, inclination, apogee (km), perigee (km), and notes.

The Aerospace Corporation Long Duration Exposure Facility (LDEF) Experiment M0003 consists of 19 subexperiments from the Aerospace Laboratories, DOD Laboratories, and contractor organizations. It was designed to study the effects of the space environment on a large variety of spacecraft materials and components, both current and developmental. The experiment was housed in four LDEF trays and contained over 1250 specimens, two data systems, and two environment exposure control canisters. Nearly identical pairs of trays were located on the leading and

trailing edges of LDEF. The materials in these trays span nearly all generic functions in spacecraft such as optics, thermal control, composites, solar power, and electronics. Effects of the space environment such as vacuum, ultraviolet, atomic oxygen, meteoroid and debris, thermal cycling, and synergistic effects on various samples are described. Summaries of the on-board data are presented DTIC

FLIGHT TESTING OF AIRBREATHING HYPERSONIC VEHICLES

John W. Hicks Oct. 1993 37 p Presented at Space Course 1993, Munich, Germany, 11-12 Oct. 1993 Sponsored by NASA, Washington (RTOP 505-70-00)

(NASA-TM-4524; Paper-37; H-1934; NAS 1.15:4524) Avail: CASI HC A03/MF A01

Using the scramjet engine as the prime example of a hypersonic airbreathing concept, this paper reviews the history of and addresses the need for hypersonic flight tests. It also describes how such tests can contribute to the development of airbreathing technology. Aspects of captive-carry and free-flight concepts are compared. An incremental flight envelope expansion technique for manned flight vehicles is also described. Such critical issues as required instrumentation technology and proper scaling of experimental devices are addressed. Lastly, examples of international flight test approaches, existing programs, or concepts currently under study, development, or both, are given. Author (revised)

SOLAR ABSORPTANCE OF OPTICAL SURFACES CONTAMINATED WITH SPACECRAFT MATERIAL OUTGASSING PRODUCTS Final Report, 8-27 Jul. 1992

W. T. Bertrand and B. E. Wood Jul. 1993 23 p

(AD-A267202; AEDC-TR-93-7) Avail: CASI HC A03/MF A01

As satellite applications become more sophisticated and satellite lifetimes are extended, the roles of contamination prediction and control become increasingly important. Contamination can alter the spectral characteristics of cryogenically cooled optical systems, increase the solar absorptance of thermal control surfaces causing the spacecraft to overheat, or degrade the power output of solar cells. The Solar Absorptance Measurements Chamber was developed to measure the change in integrated solar absorptance of aluminum coated mirrors by condensed outgassing contaminants irradiated by a solar simulator under vacuum. In previous tests, the location of the solar simulator did not allow irradiation of the sample mirror during the contamination phase. The test chamber was modified, and measurements were made to compare the solar absorptance change for samples irradiated during contamination to samples with no irradiation during contamination. Sources of the contaminants were two spacecraft materials, Furane Products Uralane 5753-AB (LV) encapsulant and Dow Corning 93-500 encapsulant. DTIC

A FEASIBILITY STUDY OF A MICROGRAVITY ENHANCEMENT SYSTEM FOR SPACE STATION FREEDOM

Preston S. Diamond and Robert H. Tolson Oct. 1993 120 p See also A93-52902

(Contract NCC1-104; RTOP 476-14-06-01)

(NASA-CR-191550; NAS 1.26:191550) Avail: CASI HC A06/MF A02

The current low frequency microgravity requirements for Space Station Freedom (SSF) call for a level of less than 1 micro-g over 50 percent of all the laboratory racks for continuous periods of 30 days for at least 180 days per year. While this requirement is attainable for some of the laboratory modules for the Permanently Manned Configuration (PMC), it can not be met for the Man-Tended Configuration (MTC). In addition, many experiments would prefer even lower acceleration levels. To improve the microgravity environment, the Microgravity Enhancement System (MESYS) will apply a continuous thrust to SSF, to negate the disturbing gravity gradient and drag forces. The MESYS consists of a sensor, throttle-able thrusters and a control system. Both a proof mass system and accelerometer were evaluated for use as the sensor. The net result of the MESYS will be to shift the microgravity contours from the center of mass to a chosen location. Results indicate the MESYS is not feasible for MTC since it will require 5,073 kg of hydrazine fuel and 7,660 watts of power for 30 days of operation during average atmospheric conditions. For PMC, the MESYS is much more practical since only 4,008 kg of fuel and 5,640 watts of power are required. Author (revised)

APPARATUS AND METHOD FOR PRODUCING AN ARTIFICIAL GRAVITATIONAL FIELD Patent Application

Jason McCanna, inventor (to NASA) 3 Jun. 1993 24 p

(NASA-Case-MSC-22021-1; NAS 1.71:MSC-22021-1;

US-Patent-Appl-SN-073847) Avail: CASI HC A03/MF A01

An apparatus and method is disclosed for producing an artificial gravitational field in a spacecraft by rotating the same around a spin axis. The centrifugal force thereby created acts as an artificial gravitational force. The apparatus includes an engine which produces a drive force offset from the spin axis to drive the spacecraft towards a destination. The engine is also used as a counterbalance for a crew cabin for rotation of the spacecraft. Mass of the spacecraft, which may include either the engine or crew cabin, is shifted such that the centrifugal force acting on that mass is no longer directed through the center of mass of the craft. This off-center centrifugal force creates a moment that counterbalances the moment produced by the off-center drive force to eliminate unwanted rotation which would otherwise be precipitated by the offset drive force. TETRAHEDRAL LANDER Patent Application

Karen L. Nyberg, inventor (to NASA) 3 Feb. 1993 18 p

(NASA-Case-MSC-22082-1; NAS 1.71:MSC-22082-1;

US-Patent-Appl-SN-012893) Avail: CASI HC A03/MF A01

An apparatus and method is disclosed for decelerating and absorbing impact of a re-entry vehicle suitable for payloads that are relatively light as well as payloads weighing several tons or more. The apparatus includes four inflatable legs displaced equidistantly from each other around a capsule or housing which contains a payload. The legs are inflated at a designated altitude after entering Earth's atmosphere to slow the descent of the re-entry vehicle. Connected between each of the four legs are drag inducing surfaces that deploy as the legs inflate. The drag inducing surfaces are triangularly shaped with one such surface being connected between each pair of legs for a total of six drag inducing surfaces. The legs have drag inducing outer surfaces which act to slow the descent of the re-entry vehicle. NASA

PULSE RESPONSE BASED CONTROL FOR MINIMUM TIME MANEUVER OF FLEXIBLE SPACECRAFT Final Report, 1 Jul. - 30 Nov. 1992

Jeffrey K. Bennighof 10 May 1993 98 p

(Grant AF-AFOSR-0297-90)

(AD-A266186; AFOSR-93-0429TR) Avail: CASI HC A05/MF A02

The pulse response based control method for minimum time maneuver of flexible spacecraft is described. This method makes it possible to obtain minimum time control profiles for linear systems solely on the basis of measured response to pulses in control inputs and gross inertial properties of the system, such as total mass or total mass moment of inertia. The accuracy with which the final state of the system can be specified is shown to be related to the observability of the system with the given outputs. A special algorithm is developed for solving the numerical optimization problem arising in this approach. For maneuver problems, nonlinear behavior is handled by explicitly modeling the deviation from linear behavior in those few modes in which it is significant. A feedback control scheme to complement pulse response based control, which is stable in the presence of nonlinear rotational stiffening effects and input bounds, is presented. Also, a near minimum time method which requires virtually no real time computation is described. Numerical examples illustrate the method and its features and extensions. DTIC

THE LAUNCH OF ELDO
John Krige Mar. 1993 38 p
(ESA-HSR-7) Avail: CASI HC A03/MF A01

The intergovernmental negotiations which led to the signature of a convention in April 1962 establishing ELDO, the European Space Vehicle Launcher Development Organization, are described. The initial program of this organization foresaw the construction of a three stage rocket capped by a satellite test vehicle, with the work on each component spread between the four major western European states. After describing the British military origins of the first stage, called Blue Streak, we shall go on to explore how the UK managed to persuade first France, then Germany, and finally Italy to participate in the program. HISTORY OF ON-ORBIT SATELLITE FRAGMENTATIONS
David J. Nauer Jul. 1992 266 p
(Contract NAS9-18209)
(NASA-CR-191644; NAS 1.26:191644; CS92-TR-JSC-007) Avail: CASI HC A12/MF A03

Since the first serious satellite fragmentation occurred in Jun. 1961, and instantaneously increased the total Earth satellite population by more than 400 percent, the issue of space operations within the finite region of space around the Earth has been the subject of increasing interest and concern. The prolific satellite fragmentations of the 1970's and the marked increase in the number of fragmentations in the 1980's served to widen international research into the characteristics and consequences of such events. Plans for large, manned space stations in the next decade and beyond demand a better understanding of the hazards of the dynamic Earth satellite population. The contribution of satellite fragmentations to the growth of the Earth satellite population is complex and varied. The majority of detectable fragmentation debris have already fallen out of orbit, and the effects of 40 percent of all fragmentations have completely disappeared. In this volume, satellite fragmentations are categorized by their assessed nature and to a lesser degree by their effect on the near-Earth space environment. A satellite breakup is the usually destructive disassociation of an orbital payload, rocket body, or structure, often with a wide range of ejecta velocities. A satellite breakup may be accidental or the result of intentional actions, e.g., due to a propulsion system malfunction or a space weapons test, respectively. An anomalous event is the unplanned separation, usually at low velocity, of one or more detectable objects from a satellite which remains essentially intact. Anomalous events can be caused by material deterioration of items such as thermal blankets, protective shields, or solar panels. As a general rule, a satellite breakup will produce considerably more debris, both trackable and non-trackable, than an anomalous event. From one perspective, satellite breakups may be viewed as a measure of the effects of man's activity on the environment, while anomalous events may be a measure of the environment on man-made objects. THE FRAGMENTATION OF KOSMOS 2163
Jan. 1992 14 p
(Contract NAS9-18209)
(NASA-CR-191643; NAS 1.26:191643; CS92-TR-JSC-002) Avail: CASI HC A03/MF A01

On 6 Dec. 1991 Kosmos 2163, a maneuverable Soviet spacecraft which had been in orbit for 58 days, experienced a major breakup at an altitude of approximately 210 km. Although numerous pieces of debris were created, the fragments decayed rapidly leaving no long-term impact on the near-Earth environment. The assessed cause of the event is the deliberate detonation of an explosive device. Details of this event are presented.

CHOOSING ESRO'S FIRST SCIENTIFIC SATELLITES
Arturo Russo Nov. 1992 53 p
(ESA-HSR-3) Avail: CASI HC A04/MF A01

The choice of the scientific payloads of the European Space Research Organization's (ESRO's) first generation of satellites is analyzed. Concentration is on those aspects of the decision process that involved more directly the scientific community and that emerged as major issues in the discussion of the Launching Program Advisory Committee (LPAC). The main theme was the growing competition between the various fields of space science within the progressive retrenching of the Organization's financial resources available for the satellite program. A general overview of the status of the program by the end of 1966 is presented. The choice of the first small satellites' payloads (ESRO 1 and 2, and HEOS-A) and the difficult definition of the TD satellite program are discussed. This part covers a time span going from early 1963 to the spring of 1966. In the second part, the narrative starts from the spring of 1967, when the decision to recommend a second HEOS-type satellite was taken, and then analyzes the complex situation determined by the crisis of the TD program in 1968, and the debates which eventually led to the abandonment of TD-2 and the start of the far less ambitious ESRO 5 project. THE EARLY DEVELOPMENT OF THE TELECOMMUNICATIONS SATELLITE PROGRAMME IN ESRO (1965-1971)
Arturo Russo May 1993 86 p
(ESA-HSR-9) Avail: CASI HC A05/MF A01

The European Space Research Organization (ESRO) was created in the early 1960's as an organization solely devoted to space science. At the end of 1966, however, after a request from the European Conference on Satellite Communications, the ESRO Council accepted to undertake a six-month study to evaluate the technical and financial implications involved in the development and launching of a few experimental communications satellites and to indicate other developments of interest in the field of application satellites. The analysis of the difficult beginning of ESRO's telecommunications program is discussed. The actual implementation of this program up to 1978 when the first experimental satellite (OTS-2) was successfully launched is discussed. Derived from text

DEVELOPMENT OF A PROTOTYPE KINESTATIC PLATFORM FOR APPLICATION TO SPACE AND GROUND SERVICING TASKS. PHASE 1: CONCEPT MODELING Final Report
J. Duffy and C. Crane Sep. 1993 53 p Original contains color illustrations
(Grant NAG10-0109)
(NASA-CR-194036; NAS 1.26:194036) Avail: CASI HC A04/MF A01; 2 functional color pages

The Center for Intelligent Machines and Robotics (CIMAR) of the University of Florida, in conjunction with Rockwell International is developing an electro-mechanical device called a Kinestatic Platform (KP) for aerospace applications. The goal of the current project is to develop a prototype KP which is capable of manipulating a 50 lb. payload. This prototype will demonstrate the feasibility of implementing a scaled up version to perform high precision manipulation of distributed systems and to control contact forces and allowable motions (rotations and translations), which is defined here as Kinestatic Control, in a six dimensional, partially constrained environment, simultaneously and independently. The objectives of the Phase 1 effort were as follows: (1) Identify specific NASA applications where the KP technology can be applied. (2) Select one application for development. (3) Develop a conceptual design of the KP specifically for the selected application. This includes the steps of developing a set of detailed performance criteria, establishing and making selection of the mechanism design parameters, and evaluating the expected system response. (4) Develop a computer graphics animation of the KP as it performs the selected application. This report will proceed by providing a technical description of the KP followed by how each of these objectives was addressed. Derived from text

PERFORMANCE OF SILVERED TEFLON THERMAL CONTROL BLANKETS ON SPACECRAFT
G. Pippin, W. K. Stuckey, and C. S. Hemminger 15 Mar. 1993 15 p
(Contract F04701-88-C-0089)
(AD-A266284; TR-93(3935)-9) Avail: CASI HC A03/MF A01

Silver-backed fluorinated ethylene propylene Teflon (Ag/FEP) thin film material was used for thermal control in many locations on the Long

Duration Exposure Facility (LDEF). The Ag/FEP registered the effects of atomic oxygen, solar ultraviolet radiation, meteoroid and debris impacts, thermal cycling, and contamination. This report summarizes the post-flight condition of the Ag/FEP, compares the results with performance on other spacecraft, and presents lifetime estimates for use under a variety of environmental exposures. Measurements of optical property and mechanical property and surface chemistry changes with exposure conditions, and their significance for design considerations and expected performance lifetimes, are reported for material flown on LDEF. The LDEF based data provides detailed information performance of Ag/FEP under relatively long term exposure in low Earth orbit. Comparison of this data with results from short term shuttle flights, Solar Max, SCATHA, other satellites, and ground based measurements is made to present a comprehensive summary of the use of this material for spacecraft applications. SOYUZ/ACRV ACCOMMODATION STUDY
Jonathan Cruz, Marston J. Gould, and Eric Dahlstrom (Lockheed Engineering and Sciences Co., Hampton, VA.) Nov. 1993 152 p
(RTOP 476-14-06)
(NASA-TM-107733; NAS 1.15:107733) Avail: CASI HC A08/MF A02

Included is a set of viewgraphs that present the results of a study conducted at the LaRC Space Station Freedom Office at the request of the Space Station Freedom Level 1 Program Office and the JSC ACRV Project Office to determine the implications of accommodating two Soyuz TM spacecraft as Assured Crew Return Vehicles (ACRV) on the Space Station Freedom (SSF) at the Permanently Crewed Capability (PCC) stage. The study examined operational as well as system issues associated with the accommodation of the Soyuz for several potential configuration options. Operational issues considered include physical hardware clearances, worst case Soyuz departure paths, and impacts to baseline operations such as Pressurized Logistics Module (PLM) exchange, Space Station Remote Manipulator System (SSRMS) attachment, Extravehicular Activity (EVA), and automatic rendezvous and docking (AR&D). Systems impact analysis included determining differences between Soyuz interface requirements and SSF capabilities for the Electrical Power System (EPS), Thermal Control System (TCS), Communications and Tracking (C&T), Audio-Video Subsystem (A/V), Data Management System (DMS), and Environmental Control and Life Support System (ECLSS). Significant findings of this study have indicated that the current AV capability of the Soyuz will need to be increased to provide adequate departure clearances for a worst case escape from an uncontrolled SSF and that an interface element will be required to mate the Soyuz vehicles to station, provide for AR&D structural loads, and to house Soyuz-to-SSF system interfaces. IMPLEMENTING A 50X50 GRAVITY FIELD MODEL IN AN ORBIT DETERMINATION SYSTEM M.S. Thesis
Daniel J. Fonte, Jr. Jun. 1993 328 p
(AD-A267548; AFIT/CI/CIA-93-089) Avail: CASI HC A15/MF A03

The Kepler problem treats the earth as if it is a spherical body of uniform density. In actuality, the earth's shape deviates from a sphere in terms of latitude (described by zonal harmonics), longitude (sectorial harmonics), and combinations of both latitude and longitude (tesseral harmonics). Operational Orbit Determination (OD) systems in the 1960's focused on the effects of the first few zonal harmonics since they represented the dominant terms of the geopotential perturbation, they were well known, and the use of a limited number of harmonics greatly simplified the perturbation theory used. The demand for increasingly accurate modeling of a satellite's motion, combined with an increase in knowledge of the geopotential and an advancement in computer technology, led to the inclusion of tesseral harmonics. The Draper Laboratory version of the Goddard Trajectory Determination System (R&D GTDS), one operational OD system, can currently implement up to a 21x21 gravity field model in its Cowell and Semianalytic Satellite Theory (SST) orbit generators. This thesis investigates the extension of R&D GTDS to include a 50x50 gravity field model in the Cowell and SST orbit generators. This extension would require code modifications in the following environments to support the various operational versions of R&D GTDS: IBM, VAX, Sun Workstation, and Silicon Graphics. DTIC

SMALL SATELLITES SYSTEMS AND SERVICES [SYSTEMES ET SERVICES A PETITS SATELLITES]
Jan. 1993 731 p In ENGLISH and FRENCH Colloquium held in Arcachon, France, Jun. 1992
(ISBN-2-85-428327-9; ETN-93-94440) Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The various documents provided at the first 'Small Satellite Systems and Services' symposium are incorporated in the present work and classified according to the themes of the symposium sessions. A synthesis by the session leaders is given at the end of each theme. Eleven sessions were held, with the following headings: system analysis and simulations, launch facilities, sciences of the Universe, Earth observation, ground facilities, radiocommunication systems and their applications, satellite architecture, subsystem technology, access to space technology, and economic aspects. The last one is a poster session. All the documents indicate a strong and active interest in small satellites, as regards ground infrastructures, radiocommunication systems, satellite architecture, and subsystem technology in particular. For individual titles, see N94-17132 through N94-17191.

SMALL SATELLITE CONSTELLATION SYSTEM: OPTIMIZATION CRITERIA
B. Pavesi and P. Palmucci *In* CNES, Small Satellites Systems and Services Jan. 1993 p 39-50 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The systematic approach adopted to implement an optimal network architecture design as conditioned by the service requirements is discussed. The methodology is outlined and key parameters are identified: service and traffic requirements, constellation parameters, system parameters such as access and modulation techniques, link budgets, channellization, signalling, and antenna configuration. The best compromise solution is derived; the system's efficiency and availability are quantified. The economic aspects are also taken into account in the evaluation of the system feasibility. ESA

AMIGAU: A PROTOTYPE TOOL AIMED AT MISSION ANALYSIS FOR SATELLITES AND SATELLITE CONSTELLATIONS [AMIGAU: PROTOTYPE D'OUTIL D'ANALYSE DE MISSION POUR SATELLITES ET CONSTELLATIONS DE SATELLITES]
Jacques Foliard, Alain Lamy, and Stephane Pascal (Societe d'Economie et de Mathematique Appliquees, Paris, France.) *In its* Small Satellites Systems and Services Jan. 1993 p 51-59 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

From current spatial mechanics studies related to orbiting mini-satellites or mini-satellite constellations, it is demonstrated that the various problems related to mission analysis are similar (i.e., phase, Sun synchronization, fuel budget, maneuvering strategies, and position locating). In order to facilitate mission analysis, a single easy-to-use tool is necessary. The AMIGAU (French acronym for mission analysis by graphics, diagrams, and tools), which includes calculation modules based on spatial mechanics formerly developed for mission analyses or operations, is described. Typical

problems of mission analysis, its context and environment, as well as AMIGAU components are discussed. Two application examples which demonstrate the interest of simulations are detailed: determination of the altitude and local hour of the phased Sun synchronized orbit of an observation satellite; and a stationkeeping study of an orbiting satellite in a phased Sun synchronized orbit. LOW EARTH ORBIT CONSTELLATIONS: ORBIT CONTROL OR NOT **c13**

Jose Radzik and Gerard Maral (Ecole Nationale Superieure des Telecommunications, Toulouse, France.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 61-70 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The aim of the study is to list the arguments for and against the adoption of orbit control. The first section is a semi-analytical calculation of the probability of visibility with minimum elevation angle of a single satellite, to be used for altitudes less than 2000 km. Section two evaluates the number of noncontrolled satellites needed to guarantee a given probability of visibility for the whole constellation. Section three gives a comparison between noncontrolled and controlled constellations in the case of very low altitudes (less than 800 km). The main problem is the effect of atmospheric drag which reduces significantly the coverage performance of the satellite at its end of life. Evaluating the semi-major-axis contraction and eccentricity evolution with time allows us to define the noncontrolled satellite constellations. ESA

IMPACT OF LAUNCHING UNCERTAINTIES ON THE VISIBILITY OF COMMUNICATION SATELLITE CONSTELLATIONS WITHOUT ORBIT CONTROL [IMPACT DES INCERTITUDES DE LANCEMENT SUR LES PERFORMANCES DE VISIBILITE DE CONSTELLATIONS DE SATELLITES DE TELECOMMUNICATIONS SANS CONTROLE D'ORBITE]

Jean Jacques DeRidder, Gerard Maral, and Chantal Tamise (Toulouse Univ., France.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 71-83 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A statistical analysis and modeling of satellite constellations without orbit control is proposed. After definition, the visibility of a satellite is calculated. Satellite displacement and launching uncertainty modeling allows statistical calculations of visibility performance criteria, which is determined by means of a numerical method. Visibility performance evolution for a constellation without orbit control is dicussed: simulating conditions, variance influence on altitude, and latitude influence are studied. Results enable the system designer to decide in favor of orbit control or not according to the service and economical constraints of the mission. ESA

RADIOCOMMUNICATION PROBLEMS OF A POSITION REPORTING AND BIDIRECTIONAL MESSAGERY SYSTEM USING VHF/UHF WITH LOW-EARTH ORBIT SATELLITES [ASPECTS RADIOCOMMUNICATIONS DANS UN SYSTEME DE LOCALISATION ET MESSAGERIE BIDIRECTIONNELLE EN VHF/UHF PAR SATELLITES EN ORBITE BASSE] **c32**

G. Lesthievent and M. Margery *In its* Small Satellites Systems and Services Jan. 1993 p 85-99 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Low Earth orbit minisatellite constellations are used for VHF/UHF links between mission centers and mobile terminals for the development of position reporting and telemetry services. Due to the nature of this task, specific constraints are imposed on the radiocommunication system. The constraints are reviewed, as well as the additive and multiplicative perturbations of the transmission channel that result in thermal and galactic noise, interferences and jammings, and ionospheric scintillation. System parameters and architecture are discussed using a 'downwards' approach to determine link performance. An analysis of the forward and return link is presented as well as computer simulation models which allow a statistical estimation of the performance in terms of acquisition ratio. ESA

N94-17137 European Space Agency, Paris (France).
SMALL LAUNCHERS (CURRENT AND FUTURE PROJECTS IN THE WORLD) [LES PETITS LANCEURS (PROJETS ACTUELS ET FUTURS DANS LE MONDE)] **c15**

W. G. Naumann *In* CNES, Small Satellites Systems and Services Jan. 1993 p 103-119 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Small satellites need launching services using small launchers capable of injecting 100 to 1000 kg into a polar orbit at an altitude of 1000 km. Operational small launchers are reviewed as well as developing and planned ones. Launcher characteristics, constraints, performance, and status are detailed. Few technical problems are encountered, as most launcher projects call for existing components and well known technologies. Most of the difficulties have come from launch site availability and from financial considerations. ESA

N94-17138 Telespazio S.p.A., Rome (Italy).
SMALL SATELLITE CONSTELLATION DEPLOYMENT STRATEGIES **c15**

Giuseppe Rondinelli and Enrico Masci *In* CNES, Small Satellites Systems and Services Jan. 1993 p 121-130 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Some optimization criteria for deployment policies of small satellite constellations are shown. The planned system (from an orbital point of view), the launcher role, and small launcher and conventional launcher characteristics are reviewed. Additionally, trade off considerations are addressed: launchers/orbit type, launcher capability/constellation implementation, launcher/launch base selection, launcher availability/constellation deployment time, launch strategy/orbit and constellation deployment time, and launch strategy/orbit and constellation requirements. Considering all the factors involved in the process, a mixed technique performed both logically and analytically allows minimization of the selected objective functions. Two primary objective functions are as follows: cost/kg on orbit and time of deployment. ESA

DELTA LAUNCH VEHICLE: ACCOMMODATIONS FOR SMALL SATELLITES **c15**

K. R. Know *In* CNES, Small Satellites Systems and Services Jan. 1993 p 131-138 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The possibility of comanifesting small satellites of different sizes and masses into low Earth orbits with the Delta launch vehicle is examined. Several benefits are offered: (1) the variety of vehicle configurations (number of strap-on solid motors and fairing diameter options) and launch sites allows more flexibility in accommodating desired physical shapes and mission orbit parameters; (2) the individual satellite launch service will be significantly less than a dedicated single launcher; and (3) the long and successful launch record of the Delta program provides the added confidence in achieving a successful program. ARIANE 5 LIGHT DERIVATIVES [LES DERIVES LEGERS D'ARIANE 5] **c15**

Jean-Marc Astorg *In its* Small Satellites Systems and Services Jan. 1993 p 139-149 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The Ariane 5 light derivatives are studied in order to complete Ariane 5

launch services with regard to medium size Sun synchronous spacecrafts (S derivative) and small satellites (P derivative). The P derivative is a three stage launcher with two solid propellant motors and a bipropellant upper stage. It is capable of placing 1 ton in a 1000 km circular polar orbit or two 450 kg payloads in the same orbit. The light derivatives are mainly derived from the Ariane 5 solid propellant booster and upper stage. The payload volume is particulary large (2.8 m internal maximal diameter, 6 m height). The light derivatives will be launched from the Ariane spaceport in Guyana. They will use Ariane 5 facilities for payload preparation and launch operation with a specific building for launcher integration. The first flight of the P derivative is scheduled for 1998. ESA

NEXT LAUNCH SYSTEM **c15**
C. Oiknine *In* CNES, Small Satellites Systems and Services Jan. 1993 p 151-160 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The NEXT launch system is proposed by Israel Aircraft Industries to provide a low cost launch service capability for small satellites. It is an adaptation of the existing Shavit 1 launcher vehicle system. The NEXT launch system incorporates modern flight proven components and has three major elements: the launcher vehicle which consists of a three stage solid rocket motor booster with a liquid bipropellant system at the upper stage; the launcher erector transporter; and the launch operations support equipment. A new approach for launch service operations allows low cost launch service and use of proven technology insures reliability. Performances and orbital accuracy are specified. ESA

SMALL MISSIONS FOR SPACE SCIENCE Abstract Only **c12**
H. Olthof *In* CNES, Small Satellites Systems and Services Jan. 1993 p 165 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

According to the recommendations of the ESA program review panel, an analysis of the interest in small missions within the European scientific community was initiated. Three actions were undertaken: a call for ideas for small missions; a workshop on 'design approaches and development philosophies of small satellites'; and a technical assessment of two examples of small satellites. From the results, a meeting of the Science Program Committee concluded that ESA should continue fostering small satellite programs and should offer limited support to the member states on a case by case basis. ESA

The Ulysses Reference Mission (URM) was initiated after NASA cancelled its contribution to the International Solar Polar Mission. A small satellite was designed to carry the five main Ulysses instruments on board and to perform scientific baseline measurements. A feasibility study was undertaken to specify the requirements for a small satellite bus, to design a modular bus unit system--the characteristics of which are reviewed, and to plan the URM mission objectives. Finally a new system of adaptable components was established as a basis for future programs. ESA

SMALL SATELLITE MISSIONS TO LONG-PERIOD COMETS **c12**
Ettore Perozzi and Eduard M. Pittich (Slovak Academy of Sciences, Bratislava, Czechoslovakia.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 181-184 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Advantages which are expected from space missions towards long period comets and the difficulties of planning such a mission are explained. Conventional missions cannot be planned due to the long waiting time for the comet to appear and the limited time span from discovery to launch. As interplanetary missions with small satellites are now feasible (Giotto experiment) the development of small launchers may solve the major difficulties regarding missions to long period comets, the only objects of the solar system that cannot be reached at present by other means. ESA

SMALL SPACECRAFT FOR PLANETARY EXPLORATION **c12**
Ross M. Jones *In* CNES, Small Satellites Systems and Services Jan. 1993 p 185-195 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

There is need for lower cost, more frequent planetary science missions to compliment the 'once a decade' large multidisciplinary missions. The Solar System Exploration Division of NASA's Office of Space Science and Applications has initiated a program of planetary missions using small spacecraft. This program is called Discovery. Conceptual designs of small spacecraft (100 to 500 kg) for potential Discovery missions to near Earth asteroids are summarized. Another class of spacecraft that could be used for Discovery missions are called microspacecraft. Microspacecraft would be compatible with small launch vehicles such as Pegasus. The term 'microspacecraft' is used here for spacecraft concepts whose mass is about 10 kg. A study of a microspacecraft for a mission to near Earth asteroids is also summarized. ESA

The results obtained from a preliminary scientific mission study realized by a small satellite in low Earth orbit and using DORIS (Doppler Orbitography and Radiopositioning Integrated from Space) is summarized. Scientific objectives are exposed: Earth gravity field, satellite orbit analysis, ionosphere, and thermosphere density variations are to be studied. The principle of the DORIS system is explained and DORIS is described in detail as well as measurement processing. The BRIDGE mission analysis involves the orbit selection from the on-orbit lifetime, the orbit characteristics, launching, satellite visibilities, constraints due to the payload and to the platform. Finally one circular and two elliptical orbits are selected. Platform predimensioning is discussed. Linking and mass budgets are presented as well as the BRIDGE platform stabilization system. ESA

COSMIC DUST AND SPACE DEBRIS MEASUREMENTS ON BOARD THE SMALL SATELLITES HITEN AND BREM-SAT **c90**
H. Iglseder *In* CNES, Small Satellites Systems and Services Jan. 1993 p 209-217 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Primary goals of the MUSES-A HITEN mission are to verify technologies and techniques required for lunar and planetary missions in the near future. One of the objectives was an experiment related with the detection and the measurement of mass, velocity and crude flight direction of micrometeroid particles with a Miniaturized Dust Detector (MDC). The experiment set up, the measuring principle and the results of two year operation are discussed; preliminary results show the cosmic dust flux versus time, particle velocity and mass; the spatial and directional distributions are presented as well as the orbital flight velocities of the particles. Space debris measurements are planned with the MDC on board of the microsatellite BREM-SAT. The two main objectives of this future mission are outlined. ESA

SYNMOD: A LOW-RESOURCE, LOW-COST MEANS OF MONITORING THE NEAR-EARTH SPACE DEBRIS ENVIRONMENT

J. Derral Mulholland (Observatoire de la Cote d'Azur, Nice, France.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 219-227 Prepared in cooperation with Institute for Space Science and Technology, Inc., Magagnose, France (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Synoptic Monitoring of Orbital Debris (SYNMOD) is a concept that envisions a network of satellites equipped with high time resolution orbital debris impact detectors based on those of the LDEF Interplanetary Dust Experiment (IDE). The ideal network consists of such devices orbiting at a wide variety of altitudes and inclinations with continuous temporal coverage. Modest downlink telemetry requirements permit rapid evaluation of the local debris environment at each spacecraft and by simultaneous analysis of the data from the entire network of the global debris environment. Installing the detectors on the solar panel backsides insures that the system can be adapted in a uniform way to a variety of large and small spacecrafts. IDE provided the first mapping of the angular distribution of small particulates in the near Earth environment, which was shown extremely nonisotropic and time variant. Most of the orbital debris is contained in clouds, some of them in eccentric orbits and/or exceeding 2000 km in extent. Their knowledge can be obtained by continual monitoring on a global network, for which SYNMOD is proposed as a basis. ESA

EARTH OBSERVATION FROM SMALL SATELLITES [OBSERVATION DE LA TERRE A PARTIR DE MINISATELLITE] **c43**

C. Vialet *In* CNES, Small Satellites Systems and Services Jan. 1993 p 259-277 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A variety of valuable Earth observation missions can be performed on the basis of existing instrument designs and with the MSS/Fairchild class 2 bus. A general description of the multimission platform and the development status is given. Optical and microwave instruments for Earth observation, ground segment, mission and control center, and payload user center are considered. Instruments were selected for their modest mass and power requirements. The multimission platform is of a modular design; the satellite is compatible with the Pegasus or Taurus launcher and can use SPOT, ERS, and LANDSAT ground stations. Satellite characteristics for along track optical stereo and for altimetry are given as an example. ESA

N94-17151 Lockheed Aircraft Corp., Palo Alto, CA.

SMALL IMAGING SATELLITE FOR EARTH OBSERVING SYSTEM ADJUNCT **c43**

Steven Kilston, Vera Kilston, and Thomas F. Utsch (Air Force Space Div., Los Angeles, CA.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 279-290 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A small multi-mission imaging satellite was developed as an adjunct to the Earth observing system constellation of moderate sized, long life sensing platforms to complement and improve support to the data collection. The satellite's electrooptical sensing payload is designed to operate in many different data collection modes; an operations mode allowing quick changes in the swath width, spatial resolution, and spectral bands being collected can optimize the system coverage. Characteristics of the reliable camera, sensor subsystem design, and sensor parameters are specified. The system, designed for 3 to 5 years lifetime, may find various applications, and could be used to support military data needs in event of a military operation. ESA

N94-17152 Centre National d'Etudes Spatiales, Toulouse (France).

ADEQUATION OF MINI SATELLITES TO OCEANIC ALTIMETRY MISSIONS [MINISATELLITES ET ALTIMETRIE OCEANIQUE OPERATIONNELLE: L'ADEQUATION]

G. Bellaieche and J. P. Aguttes *In its* Small Satellites Systems and Services Jan. 1993 p 291-302 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Association of the mini satellite concept and oceanic altimetry missions is discussed. Mission definition and most constraining requirements (mesoscale for example) demonstrate mini satellites to be quite adequate for such missions. Progress in altimeter characteristics, orbit determination, and position reporting allow consideration of oceanic altimetry missions using low Earth orbit satellites. Satellite constellation, trace keeping and orbital period, and required payload characteristics are exposed. The mission requirements covering Sun synchronous orbit, service area, ground system, and launcher characteristics as well as constellation maintenance strategy are specified. Two options for the satellite, orbital mechanics, propulsion, onboard power and stabilizing subsystems, onboard management, satellite ground linkings, mechanical and thermal subsystems, budgets, and planning are discussed. ESA

N94-17153 Societe Anonyme d'Etudes et Realisations Nucleaires, Limeil-Brevannes (France).

SYDONI: AN INTENSIFIED SYSTEM FOR NIGHT OBSERVATION [SYDONI: SYSTEME D'OBSERVATION NOCTURNE INTENSIFIE]

A. Colmon, M. Tissot, and P. Turon *In* CNES, Small Satellites Systems and Services Jan. 1993 p 303-315 In FRENCH (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

An onboard observation device for small satellites is proposed. Called SYDONI, it uses image intensification techniques. Advantages of the night imagery, photometric magnitudes, intensifier characteristics parameters and performance, and signal to noise ratio are discussed. Possible applications are listed. A meteorological mission is selected as a qualification mission; it uses microsatellites and allows demonstration of intensified observation interest and possible use in space. Performances required for the instruments, the camera, the attitude control, and the signal processing as well as platform characteristics are discussed. Possible improvements concern higher signal to noise ratio, larger observation field and higher resolution, improved attitude control, and higher shooting frequency; possible solutions are outlined. ESA

N94-17154 VEGA Space Systems Engineering Ltd., Harpenden (England).

A PROPOSED GROUND SEGMENT DESIGN FOR SMALL SATELLITES **c14**

R. S. Thompson, C. J. Ashton, and A. N. Pidgeon *In* CNES, Small Satellites Systems and Services Jan. 1993 p 321-329 (For primary document see N94-17131 03-18)

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

For missions involving small low cost satellites under development, a low cost ground segment comprising an integrated spacecraft control system and ground station based on commercial hardware, making use of modern software technology, and collocating and integrating both the ground station and mission control system, is proposed. A reduced cost antenna system and low cost solid state amplifiers are used as ground station components. The spacecraft control system makes use of standard workstations, configurable software, graphical user interfaces, and automated procedure execution. The cost of the system is still further reduced by collocating

both the spacecraft control system and the ground station, thus simplifying the interfaces. The separation of these components is still possible for missions such as polar orbiting ones. ESA

N94-17155 INISEL, Torrejon de Ardoz (Spain).
GROUND SEGMENT DEFINITION FOR THE SPANISH SMALL SATELLITE PROGRAM (MINISAT) **c14**
F. Cancillo, L. Guzman, and L. A. SanJose *In* CNES, Small Satellites Systems and Services Jan. 1993 p 331-338 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The ground segment approach considered for the Spanish program of small satellites (MINISAT), aimed at the development of a general purpose platform to cover a wide range of missions from digital communications to astronomy and Earth observation, is addressed. Mission scenario and general requirements on the ground segment are specified. Architecture of the ground station, the Earth station structure, and control center design are discussed. The payload control center is described in detail. ESA

N94-17156 Centre National d'Etudes Spatiales, Toulouse (France).
OREMUS: PROTOTYPE OF AN ORBIT DETERMINATION CENTER DEDICATED TO MINI-SATELLITE CONTROL [OREMUS: PROTOTYPE DE CENTRE D'ORBITOGRAPHIE POUR LE CONTROLE DE MINISATELLITES] **c14**
Francois Laporte, Genevieve Campan, and Huguette Conessa *In its* Small Satellites Systems and Services Jan. 1993 p 339-347 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The OREMUS project aims to achieve at moderate cost a ground segment prototype for the purposes of orbiting satellite operations. In order to demonstrate the feasibility of a general system capable of satisfying the requirements of various users, main functions to be improved are data acquisition, orbit restitution, orbital maneuver calculations, and orbit linked expected operations. MERCATOR system architecture, components, capabilities, interest, and performance are recalled as well as the OOC (Operational Orbit determination Center) needs as regards the software. Characteristics and advantages of a new man machine interface called SISSI are presented. The OREMUS general system is based on MERCATOR and SISSI functions, and on the recovery of former modulus used in spatial mechanics. Descriptor files are documented by the users. Prototype main functions, data acquisition, orbit restitution, attitude restitution, orbital maneuver calculations, orbit linked expected operations, file management, and parameters graphic visualization are available in a control ground segment. These functions are performed by means of modulus; the linking and interfaces of which are managed by the man machine interface. ESA

REGULATION OF LOW EARTH ORBIT SATELLITES
Don Jayasuriya *In* CNES, Small Satellites Systems and Services Jan. 1993 p 377-384 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Allocation of a number of frequency bands within which low Earth systems could operate was made to the mobile satellite service by the WARC-92 conference. These allocations and their associated inter and intra-service frequency sharing difficulties are described. Former radio regulations have served adequately for the satellite systems operated from the Geostationary Satellite Orbit (GSO); WARC-92 adopted an interim regulatory system for non-GSO satellite networks. The operation of Low Earth Orbit (LEO) systems are subjected to a number of provisos relating to the protection of planned or existing services; prior to their implementation in LEO, they have to show the possibility of operating within these provisos. A way to resolve difficulties arising from the use of certain frequencies and the approval of terminals are prerequisites for paneuropean operations. ESA

Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

An experimental communication network using microsatellites is studied to solve the problems inherent in the use of geostationary satellites. A few microsatellites pick up and deliver voice and digital information from/to ground stations, and/or from/to satellites. A microsatellite features twin structures of twenty six hedron connected to each other by an expanded mast; it is 50 kg of dumbbell shape. A total of 9.6 kbps and 1.2 kbps are used for the ground link and the intersatellite link respectively with onboard digital processing techniques. The formation of the microsatellites in one orbit is used tc widen the real time communication area. A possibility of a delay time reduction for package message communication is expected using the intersatellite link. ESA

N94-17161 Italspazio, Rome (Italy).
LEOCOM-SPES: LOW COST MESSAGE COMMUNICATIONS **c32**
G. Barresi, L. Caporicci, R. DelRicco, S. DiGirolamo, B. Pavesi, and G.

Rondinelli *In* CNES, Small Satellites Systems and Services Jan. 1993 p 393-404 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

For the user categories which do not need real time connections, LEOCOM-SPES (Space Pony Express) is an economic and attractive personal communications system based on a sparse constellation applicable to message/data communications. The system architecture, the major system elements, the orbit and constellation selection, the system implementation, the ground segment, the user terminal, the network operation, and traffic scenario and requirements are outlined. Satellite and launch costs, investment costs for the central control station, and user charges are also discussed. To conclude, the Leostar spacecraft performances are summerized: Leostar is a stabilized satellite designed for operation in low altitude Earth orbits. ESA

TAOS (S80): A (LEO-MSS) SYSTEM FOR POSITION REPORTING AND TELEMANAGEMENT SERVICES [TAOS (S80): UN SYSTEME LEO-MSS POUR DES SERVICES DE LOCALISATION ET DE TELEGESTION] c32
A. Gautier and P. Dumont *In its* Small Satellites Systems and Services Jan. 1993 p 405-415 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A position reporting and telemanagement system based on the use of minisatellites (mass less than 150 kg) with limited investment and operation costs is presented. The system is designed from an analyses of market study results. The space segment is composed of a LEO-MSS (Low Earth Orbit Mini Satellite System) constellation: solution advantages are reviewed. Frequency band regulations and frequency allotment are specified. The space segment (constellation, satellite platforms), ground segment (mission and control), mobile terminal stations (connecting links, position reporting through Doppler/distance or external measurements) are described. Forward and return link budgets and communication protocols are presented. The system performances as regards capacity, response time, availability, and reliability are specified. A feasibility study using S80T, a meteorological satellite, investigates the two critical points underlined in the preliminary study. ESA

THE ORBCOMM SYSTEM c32
Martin Deckett *In* CNES, Small Satellites Systems and Services Jan. 1993 p 417-426 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The objectives, architecture, characteristics, performance, and costs of the ORBCOMM data communications and position determination system designed to bring low cost mobile communications to every country throughout the world are outlined. The system uses a constellation of small satellites in low Earth orbits, operating at VHF, as relays for the ORBCOMM network. On the ground, a simple Network Control Center (NCC) is connected to gateway Earth stations. The user needs a desk top computer at central office, connected to the NCC computer, and pocket size remote terminals. Three generic services can be provided: SecurNet for emergency alerts, MapNet for position reports, and DataNet for two way data transmission. Coverage, outage periods, choices made for ORBCOMM and capital and operating costs are also discussed. ESA

MAGSS-14: MEDIUM ALTITUDE GLOBAL MOBILE SATELLITE SYSTEM WITH ENHANCED REGIONAL COVERAGE c32
J. Benedicto, J. Fortuny, and P. Rastrilla *In* CNES, Small Satellites Systems and Services Jan. 1993 p 427-436 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The basic parameters and performance of a Medium Altitude Global Satellite System (MAGSS-14) considered as an effective way to provide voice communications services to users equipped with handheld and portable terminals are described. MAGSS-14 is based on 14 medium size satellites in a Medium Earth Orbit (MEO) constellation, and offers significant advantages in terms of gradual buildup and global coverage. The constellation parameters are optimized to enhance the coverage in terms of minimum elevation angle in the regions contained between 30 and 60 deg latitude. Network topology, payload design, link budgets, and system capacity are also discussed. ESA

N94-17165 Italspazio, Rome (Italy).
FEASIBILITY STUDY OF A PERSONAL COMMUNICATIONS SYSTEM IRIDIUM-LIKE c32
L. Caporicci, R. DelRicco, S. DiGirolamo, C. Soddu, and G. Pondinelli *In* CNES, Small Satellites Systems and Services Jan. 1993 p 437-449 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A candidate architecture applicable to personal communications systems, via Low Earth Orbit (LEO) satellites is outlined. The concept of the IRIDIUM Motorola system has been adopted as derived from the available public documentation. The following topics are covered: system architecture (IRIDIUM like concept) and scenario; constellation characteristics, user links, coverage and frequency reuse; Leostar-E spacecraft and payload architecture definition; traffic management (access, routing, networking); and organization aspects and manufacturing strategies. Additional efforts are required in order to assess a convenient cost/technology tradeoff. ESA

S 80/T: A MICRO SATELLITE SYSTEM COMBINING HIGH PERFORMANCES AND LIMITED RESOURCES [S 80/T: UN MICRO-SATELLITE SYSTEME QUI COMBINE HAUTES PERFORMANCES ET RESSOURCES LIMITEES]
Jean-Claude Llorens *In its* Small Satellites Systems and Services Jan. 1993 p 451-458 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The mission of the experimental technological microsatellite S80T is specified: 148 to 149.9 MHz frequency band analysis and modulation experiments. The system is described: platform, payload, data acquisition, satellite control, and user ground station. The spectral analysis of the frequency band is performed by means of statistical treatments of the noise at the satellite repeater entry, short duration event treatment, and treatments using time signals; calibration strategy, measurement connections between the real power at the repeater entry and the noise power picked up by the antenna, measurement sequencing, and exploitation are described. Characteristics of the main elements of the user ground station are specified: telecommand, telecontrol, tracking, interfacing computer, measuring equipment and techniques. Project development, management, quality and reliability are also outlined. ESA

N94-17167 Ellipsat Corp., Washington, DC.
THE ELLIPSO (TM) SYSTEM: ELLIPTICAL LOW ORBITS FOR MOBILE COMMUNICATIONS
David Castiel *In* CNES, Small Satellites Systems and Services Jan. 1993 p 459-463 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The ELLIPSO system is aimed at providing mobile voice services via satellites located in low Earth elliptical orbits and operating in the 1610 to 1625.5 MHz and 2483.5 to 2500 MHz bands. Orbital characteristics and time coverage over northern and southern latitudes are outlined. ELLIPSO uses Code Division Multiple Access (CDMA) within frequency segments to achieve an efficient FDMA (Frequency Division MA)/CDMA scheme. ELLIPSO satellites and ground control station equipment are also described. ELLIPSO also supports position determination embedded in the overall system, according to a concept called the Geobeacon system: position detection is obtained through measurements of time difference of arrivals and of frequency difference of arrivals. ESA

STARSYS: A VIEW AFTER WARC-92 c32
Ashok Kaveeshwar and Raul Rodriguez *In* CNES, Small Satellites

Systems and Services Jan. 1993 p 465-472 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The STARSYS system is aimed at providing low cost global positioning and messaging by satellite. STARSYS is a data only system using very brief message transmission times. Code Division Multiple Access (CDMA) is used for frequency sharing; it enables transmitted data to be coded for unique user identification and also to employ Doppler and radio ranging to determine the geographical location of a transmitting terminal. The STARSYS system is composed of the field receiver/transmitter, the Low Earth Orbit (LEO) satellite constellation and the ground station elements. Each message transmission is able to contain up to thirty two digital characters. Market applications are numerous: theft control, vehicle and logistic tracking and messaging, personal communications, utility and environmental data acquisition and transfer. Co-primary frequency allocation at WARC-92 accelerated interest for potential customers and investors, although the amount of frequency allocation (less than 1 GHz) is small. ESA

UoSAT: A DECADE OF EXPERIENCE PIONEERING MICROSATELLITES
J. M. Radbone (Surrey Univ., London, England.) and M. N. Sweeting (Surrey Univ., London, England.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 477-487 Prepared in cooperation with Surrey Univ., Guildford, England (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Two satellites constructed as examples of low cost missions are examined and the technical and management techniques employed are described. Following first UoSAT missions, KITSAT-A is an experimental mission, S80/T a demonstration mission to evaluate the use of VHF frequencies for future low Earth orbit systems and CERISE, a modified microsatellite platform, will carry a classified payload. All these satellites are based on UoSAT-5 platform. Key technical and management issues for successful microsatellite missions are reviewed: simple interfaces, flexible design, control of requirements and modularity, quality and product assurance for the technical aspect, contract conditions, project length, efficient communications, integrated and co-located team, flexibility of organization and personnel for the management conditions. ESA

CERISE MICROSATELLITE SYSTEM [LE SYSTEME MICROSATELLITE CERISE]
J. Kaced *In* CNES, Small Satellites Systems and Services Jan. 1993 p 489-496 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The main CERISE objective is measurement and characterization of the radioelectrical environment onboard a low orbit satellite in a wide frequency band. It involves a microsatellite with a mass less than 50 kg, microsatellite command/control, a ground station for telemetry scientific exploitation. Mission design and constraints are reviewed: satellite orbit in terms of the launch opportunity, no orbit control, simplified attitude control, onboard data storage capacity, short life time, low cost, launch opportunities. CERISE system is built from the UoSAT-5 concept improved as regards electrical power, flight software, telemetry/telecommand frequency modifications. Details of the CERISE payload (computer, hyperfrequency sensor, onboard testing and qualification) and groundstation (microsatellite position acquisition, orbital acceptance, telemetry exploiting unit) are dealt with. ESA

IMPACT OF ADVANCES IN TECHNOLOGY ON FUTURE SPACECRAFT DESIGN
F. Gampe and G. Lippner (Dornier System G.m.b.H., Friedrichshafen, Germany.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 497-514 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The status of the ESTEC study of the title is presented. The role of the study within the small satellite systems and services is shown, main topics, objectives and approach are summarized. Advances in technology are surveyed, followed by recommendations for an advanced engineering approach including a survey of launchers and of application fields, by a pool of potential model missions. Three of them were selected for a detailed analysis: model missions and advanced technology, advanced design, launch opportunities, the ground segment approach and the commercial approach are discussed. Potential new services are identified and payload characteristics analyzed for the reference missions. A set of reference mission requirements is established for case studies. ESA

S-80: A SATELLITE FOR LESS THAN 50 MF [S-80: UN SATELLITE A MOINS DE 50 MF]
A. Lamothe *In* CNES, Small Satellites Systems and Services Jan. 1993 p 515-520 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The S-80 is a localization system for mobiles using a constellation of small low Earth orbiting satellites. The main objective of the definition study of the space segment is the design of the S-80 satellite for a cost less than 50 MF. The objective was achieved by a specific technical approach; furthermore the satellite offers a wide mission capacity. Main specifications of the S-80 system are recalled: constellation characteristics, payload, schedule, launch opportunities. The ways to achieve the cost objective are addressed: simple technology, adequate electronics, integrated colocated teams, adequate quality policy. Expertise inherited from former projects such as EOLE or ARESENE is recalled. S-80 satellite elements, characteristics and performance are specified. ESA

SMALL SATELLITE MODULAR DESIGN AND APPLICATION PROSPECT
Jie Yuan and Jin-Jun Chen *In* CNES, Small Satellites Systems and Services Jan. 1993 p 521-531 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A small satellite modular architecture is introduced, which is based on systematically analyzing the subsystem functions of small satellites. A whole spacecraft is divided into three modules: the payload module, the attitude control module and the common service module. The payload module offers three versions to select according to payload mass; the attitude control module offers gravity gradient modules, spin stabilized modules and two types of three axis stabilization module; common service module is the small satellite control center including control system, power system and TTC (Telemetry, Tracking and Control) system. Several basic module configurations are possible: gravity gradient model, spin stabilized model, the payload module mass varying between 50 to 150 kg. The use of a Chinese launch vehicle to launch these modular small satellites is possible. Small satellite applications in the military, civil and scientific fields are prospected. ESA

Passoni (Centro Informazioni Studi Esperienze, Milan, Italy.) et al *In* CNES, Small Satellites Systems and Services Jan. 1993 p 537-546 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The GaAs solar array of ARSENE, a radioamateur spin stabilized spacecraft, is presented. The solar array uses typical Liquid Phase Epitaxy (LPE) solar cells and consists of six body mounted solar panels; each panel comprises an aluminum honeycomb substrate with aluminum skins insulated on the active area. For the qualification and acceptance of the ARSENE solar array, an engineering solar panel was submitted to the qualification tests including thermal vacuum, thermal shocks. The flight units are submitted to the thermal vacuum test. The final acceptance tests

include rotational, acoustic and vibration tests performed at satellite level. Predicted power output, GaAs solar cell manufacturing, solar panel assembly and testing are discussed. ESA

SMALL SATELLITE NICKEL-HYDROGEN AND NICKEL-METAL HYDRIDE POWER APPLICATIONS **c20**
William Dean Cook and Dwaine Coates *In* CNES, Small Satellites Systems and Services Jan. 1993 p 547-556 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Nickel and silver-metal hydride batteries are being developed for aerospace applications. Metal hydride batteries offer a number of advantages over other aerospace battery systems. Nickel-metal hydride batteries have twice the gravimetric energy density of nickel-cadmium and twice the volumetric energy density of nickel-hydrogen. Silver-metal hydride batteries have the potential of three times the energy density of nickel-metal hydride and exhibit superior charge retention characteristics. Aerospace metal hydride batteries are hermetically sealed, operate at low pressure and are prismatic in geometry. They exhibit excellent overcharge and overdischarge capability. Preliminary calorimetry data indicates superior thermal performance as compared to nickel-cadmium and nickel-hydrogen batteries. Some initial AC impedance spectroscopy work has been completed on both metal-hydrogen and metal-hydride battery systems. The objective of current programs is to develop high energy density, long cycle life metal-hydride batteries for the aerospace market and to establish a testing database to support future applications. ESA

A POWER SYSTEM FOR A MICROSATELLITE **c20**
Dan Olsson *In* CNES, Small Satellites Systems and Services Jan. 1993 p 557-566 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A power system for a microsatellite was designed for the Space Technology Research Vehicle (STRV-1) mainly aimed at technology demonstration experiments and studies of radiation effects and planned to be launched into geostationary transfer orbit. The low average solar array power (25 W) and the small volume allocation of the power system electronics (2.8 dm cubed) became a challenge when trying to produce a failure tolerant power system. The power system elements: shunt regulator, battery discharge regulator, power distribution, solar array, battery, and their management and protection are described. Power system performance and growth potential are also discussed. After several simplification iteractions, a modular power electronics system with a high degree of failure tolerance, with a mass less than 2.5 kg and an internal power consumption less than 3 W was developed. ESA

N94-17177 INISEL, Torrejon de Ardoz (Spain).
DATA HANDLING STRATEGY FOR THE SPANISH SMALL SATELLITE PROGRAM (MINISAT) **c82**
X. Lobao and L. Pina *In* CNES, Small Satellites Systems and Services Jan. 1993 p 567-575 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The data handling approach considered for the Spanish program of small satellites, aimed at the development of a general purpose platform to cover missions varying from digital communications to astronomy and Earth observations is described. It consists of the centralization of the platform intelligence in the data handling computer; as a result, the computer is devoted to several mission dependent functions besides its normal data handling functions: attitude determination and control, thermal control, power distribution control, processing of payload mission data. Data handling system, subsystems, basic characteristics, connection to the data handling users, onboard computer structure are discussed. Solid state memory devices are used to allow the required high data capacity while keeping reasonable mass, size and power budgets. ESA

THE STRV ON BOARD DATA HANDLING (OBDH) SYSTEM: AN INTRODUCTION **c82**
H. G. Andrews *In its* Small Satellites Systems and Services Jan. 1993 p 577-578 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The operation of the Space Technology Research Vehicle (STRV) On Board Data Handling (OBDH) system is outlined. STRV is a 50 kg satellite designed to research and demonstrate new and improved technologies. OBDH system consists of six functionally separate units: the uplink unit, two on-board computers, the command distribution unit, the data acquisition unit, the downlink unit. They are described and their function is outlined. The OBDH system supports the data processing and control requirements of each STRV equipment. ESA

N94-17179 Aerospatiale, Cannes (France).
A MINI SATELLITE CALLED ARSENE: THE WAY TO MAKE IT AT A MINIMUM COST [UN MINISATELLITE NOMME ARSENE: COMMENT LE REALISER A COUT MINIMUM]
Jean-Paul Rihet and Jean-Pierre Redon (Centre National d'Etudes Spatiales, Toulouse, France.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 583-600 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The context of the radioamateur ARSENE project is recalled. The ARSENE idea, concept, specifications, mechanical and electrical architecture, placement in final orbit and station keeping as well as financing are discussed. The ways used to achieve ARSENE at minimal cost are explained: solutions for mechanics, integration methods, project management by industry, precision, quality, costs and the acquired expertise as regards industry and project management are dealt with. ESA

N94-17180 Technische Univ., Berlin (Germany).
TUBSAT: LOW COST ACCESS TO SPACE TECHNOLOGY
U. Renner, B. Luebke-Ossenbeck, and P. Butz *In* CNES, Small Satellites Systems and Services Jan. 1993 p 601-610 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The TUBSAT design philosophy, that provides at affordable cost conditions all necessary services to the customer, is based on the balance between low cost experiments, low cost launch opportunities (secondary payloads), and low cost space platforms. Design concept, launch opportunity, volume, mass, electrical power supply, thermal control, TTC (Telemetry, Tracking and Control), data handling, and attitude control are discussed. A high attitude control accuracy to any desired direction is required. Using TUBSAT-A prototype, the design concept was verified, data handling and the three axis sensor were qualified. ESA

STANDARD PLATFORMS FOR SMALL SATELLITES [PLATES-FORMES STANDARDS POUR PETITS SATELLITES]
Marc Schaefer *In* CNES, Small Satellites Systems and Services Jan. 1993 p 611-616 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Platforms usable for various scientific or civil missions are proposed by the team responsible for the SARA (French acronym for satellite amateur radio astronomy) project. Classical solutions are studied to be adapted to launcher special interfaces. A three axis stabilized platform is selected as an example of the low cost microsatellite possibilities: the frame, the precision of the attitude control, the pitch, roll and yaw stabilization through gravity gradient, the payload mass and possibilities, and the characteristics of the equipment are discussed. Possible applications are outlined: orbital component tests, Earth observations, and electronic mailsystems. Low costs, short development duration, and launch possibilities are mentioned. Achievement of advanced platforms with high pointing and attitude control performance is possible. ESA

N94-17182 Instituto Nacional de Tecnica Aeroespacial, Madrid (Spain).
MINISAT PROGRAMME
Jose M. Dorado *In* CNES, Small Satellites Systems and Services Jan. 1993 p 617-623 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The objective of the MINISAT program is to obtain the necessary elements to perform space missions in a way that offers payload support capabilities similar to those of a 'normal' mission, shorter delays and lower costs. A system including a space platform and a ground segment for orbit and mission control, both with a high degree of standardization is a first objective. Concept of the MINISAT platform is discussed; program status is outlined. Main characteristics of the MINISAT platform are specified: orbit, launchers, applications, dimensions, mass, electrical power, payload data, stabilization, and propulsion. ESA

N94-17183 Defence Research Agency, Farnborough (England). Space Sector.
THE SPACE TECHNOLOGY RESEARCH VEHICLE: DEVELOPMENT STATUS
K. A. Ryden *In* CNES, Small Satellites Systems and Services Jan. 1993 p 625-630 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

The Space Technology Research Vehicles (STRV's) under development are described and the up to date technical status is detailed. The two vehicles are to carry into orbit a range of new technology which requires in-orbit evaluation prior to much larger and more expensive missions. Structure power system, radio frequency system, onboard data handling system, attitude control system, experiments and ground segment are discussed. The new technologies include radiation-resistant microelectronics, radiation monitoring instruments, advanced structural materials, electrostatic hazard measuring instruments, alleviation techniques, and new power system components. ESA

ALEXIS AND HETE: TWO SMALL, LOW COST, SCIENTIFIC SATELLITE SYSTEMS
Francois Martel and Rick Fleeter *In* CNES, Small Satellites Systems and Services Jan. 1993 p 639-649 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

ALEXIS and HETE are two examples of integrated space and ground station system designed for independent use by research institutions. ALEXIS was designed as a space platform carrying telescopes for technology testing and astrophysical observations. It is schematically presented; specifications are summarized and the ground station design is outlined. The HETE principal mission is the detection and precise location of the sources of gamma ray bursts, using an array of gamma detectors, an imaging x ray telescope and four telescopes. General specifications are given; improvements compared to ALEXIS system are detailed, in particular the structure and specific objectives of the twenty ground stations. Some information is given concerning planning and development budget. ESA

TITUS: A MICRO-SATELLITE FOR TECHNOLOGY DEMONSTRATION
M. Moreliere and R. Bertrand *In* CNES, Small Satellites Systems and Services Jan. 1993 p 651-657 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

TITUS, the first representative of a small satellite family is designed as a microsatellite (50 kg) to be launched by Ariane-4 or Pegasus to offer opportunities for technology demonstration in Earth orbit. TITUS is to be injected into geostationary transfer orbits or into Sun synchronous orbits in order to cross the Polar Horn, the South Atlantic Anomaly or the Van Allen Belts with each revolution; both orbits allow to demonstrate or to qualify space equipment such as electrical and electronic components, solar cells, batteries, sensors, microwave components, and mechanical equiment. TITUS system specifications, mission aspects and modular bus design are discussed. An example of a gravity gradient stabilized platform is detailed. TITUS project characteristics are summarized. ESA

N94-17187 Orbital Sciences Corp., Fairfax, VA.
BIG RESULTS WITH SMALL SPACE SYSTEMS: WHAT SMALL SYSTEMS ARE DOING TODAY
Gilbert D. Rye and Henry F. LeMieux *In* CNES, Small Satellites Systems and Services Jan. 1993 p 665-684 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Emerging customer needs in small space systems and the capabilities that evolved in response to these needs are reviewed. The benefits realized in communications, observation and remote sensing, space research and experimentation are described; space system designs and mission objectives, instrumentation requirements, and spacecraft characteristics are detailed. Examples of space products and services are discussed: Pegasus, Taurus and PegaStar characteristics and capabilities, turnkey and space based services. Trends for the future are outlined: increasing capabilities, system sophistication, spacecraft mass, and bus performance. ESA

N94-17188 Bureau Veritas, Courbevoie (France).
SMALL SATELLITE PRODUCT ASSURANCE [L'ASSURANCE PRODUIT DES PETITS SATELLITES] **c38**
J. DeMontlivault and Jacques Cadelec (Calireal, Palaiseau, France.) *In* CNES, Small Satellites Systems and Services Jan. 1993 p 685-694 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

In order to increase the interest in small satellites, their cost must be reduced; reducing product assurance costs induced by quality requirements is a major objective. For a logical approach, small satellites are classified in three main categories: satellites for experimental operations with a short lifetime, operational satellites manufactured in small mass with long lifetime requirements, operational satellites (long lifetime required), of which only a few models are produced. The various requirements as regards the product assurance are examined for each satellite category: general requirements for space approach, reliability, electronic components, materials and processes, quality assurance, documentation, tests, and management. Ideal product assurance system integrates quality teams and engineering teams. ESA

N94-17189 Intespace, Toulouse (France).
ENVIRONMENT TESTS FOR MINI SATELLITES [ESSAIS D'ENVIRONNEMENT DES MINI SATELLITES]
Gerard Boures and Joseph Merlet *In* CNES, Small Satellites Systems and Services Jan. 1993 p 695-701 In FRENCH (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

A global approach integrating from the design test methods and equipment and measuring sensors for lower test costs and duration is

proposed: defining first the test program through a customized logical analysis; improving the global process by minimized acceptance tests (especially mechanical tests); using qualification tests for the first model and acceptance of the recurrent models through a comparison with the first model; reinforcing design test links by improving data processing and data communications; and simplifying and optimizing tasks. Simpler thermal tests, fewer measurement points, and use of 'lost' sensors are examples. These could speed up the satellite achievement and lower the corresponding costs. ESA

COST DRIVERS: WHY DO CONVENTIONAL SATELLITES COST SO MUCH? c83
Chris Elliott *In* CNES, Small Satellites Systems and Services Jan. 1993 p 703-708 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

From discussions with U.S. and European specialists, it was concluded that a positive feedback mechanism systematically forces space missions to become more expensive, to take longer time to execute, while they do not satisfy their user needs. The mechanism is analyzed and consequences for the conduct of the projects are explained. In spite of reasonable decisions at each stage of the project design and planning the costs are mounting in a 'vicious' spiral. Five major changes needed to put the costs onto a down spiral are discussed: users to determine needs, failures are tolerated, appropriate technology is used (maximum use of already existing devices), missions dedicated to fewer payloads, viticus, short project duration with small teams involved, preferably collocated. As a result, costs come down: the 'virtuous' spiral. ESA

N94-17191 Euroconsult, Paris (France).
KEY TRENDS OF THE SMALL SATELLITE MARKET c83
Stephane Chenard *In* CNES, Small Satellites Systems and Services Jan. 1993 p 709-722 (For primary document see N94-17131 03-18)
Copyright Avail: Issuing Activity (CEPADUES-Editions, 111 rue Nicolas-Vaquelin, 31100 Toulouse, France)

Characteristics of the small satellite families (minisatellites, microsatellites, nanosatellites plus the Delta class) are given. In spite of some adverse technology trends, the financial and operational advantages of the small satellites are solid: downsizing of programs such as the Earth observation system, new available launch options, progressive build-up of the satellite constellations, and progress at equipment level (onboard data processing capacity, solar array specific specific power). The five families of applications (in orbit technology demonstration, gap fillers, overlays and 'augmentsats', niche applications, start-up entrepreneurs, use of more expensive and sophisticated systems) are discussed, as well as their impact on the satellite industry and on the launch industry. Possible market development is outlined. ESA

SPACE SYSTEMS ENVIRONMENTAL INTERACTION STUDIES
M. A. Morgan, Alan C. Huber, John O. McGarity, David J. Sperry, and Scott J. Moran 12 Jan. 1993 36 p
(Contract F19628-91-C-0112)
(AD-A267280; PL-TR-93-2006; SR-1) Avail: CASI HC A03/MF A01

Under Task 1, the Photovoltaic Array Space Power Plus Diagnostics (PASP Plus) experiment, encompassing most of Amptek's effort in the report period, Amptek has done the following: (1) designed and built the experiment controller; (2) provided an electrostatic analyzer (ESA), two QCM's, and three calorimeters (CAL's); (3) worked with PL/GPSP on testing and integrating PASP Plus into the APEX satellite; and (4) provided ground support equipment for spacecraft integration and mission operation. The controller is comprised of a central processing unit, an array biasing and electrometer unit, an array 1-5 curve measurement unit, a power conversion unit, and interfaces to the 16 array modules, ten PASP Plus instruments (not including the Dosimeter), and the APEX spacecraft. The PASP Plus Controller and the ten other instruments it controls (Sun Sensor, Langmuir Probe, ESA, Transient Pulse Monitor, Electron Emitter, 2 QCM's, 3 CAL's) are described in detail, giving size (dimensions), weight, data rates and outputs, and input power requirements. On Tasks 2 and 3, at a much lower level of effort, Amptek supported PL/GPSP's work on the Charge Hazards and Wake Studies (CHAWS) experiment (O to -5000 V sweep power supply and engineering assistance) and on the Space Wave Interactions with Plasmas Experiment (SWIPE). DESIGN OF A FLUID ELASTIC ACTUATOR WITH APPLICATION TO STRUCTURE CONTROL M.S. Thesis
Mark K. Ciero May 1993 152 p
(AD-A267649) Avail: CASI HC A08/MF A02

An elastically deformable pressure vessel is used as an actuator. The internal pressure is controlled hydraulically via force applied to an external bellows. The resulting elongation of the vessel is a linear function of the input force, and depends on the physical properties of the vessel, fluid, and bellows. The design includes an orifice through which fluid flows adding damping to the actuator. Mathematical models of the actuator are developed which relate performance of the actuator to its geometry and material properties. A static analysis yields the linear relationship between the commanded input force and the resulting elongation of the vessel. A model of the passive (no input force) response of the actuator indicates it will act as a passive damper. The active response (application of a dynamic input force yielding a dynamic elongation) is limited in frequency by the orifice damping. Strategies for optimizing the actuator size and material properties are developed from the models. Actuators manufactured with differing materials and fluids were tested. The static results are linear and matched the analysis. The passive results and the model predictions confirm that the configuration of the actuators, as built, is poor for passive damping. The correlation between the model and active experiments is excellent. Actuation bandwidth is shown to be selectable by selecting orifice size. Tailoring the material properties of the vessel by the use of optimally designed composite laminates results in a factor of two improvement in the performance. The actuator is useful for structural control. Its performance is comparable to other available actuators, it is constructed of off-the-shelf hardware, and it has the advantages of a built-in frequency limit and easily customizable performance characteristics. (Grant AF-AFOSR-0340-87)
(AD-A267268; AFOSR-93-0462TR) Avail: CASI HC A05/MF A01

Future solar arrays are being designed for much higher voltages in order to meet high power demands at low currents. Unfortunately, negatively biased high voltage solar cells have been observed to arc when exposed to the low earth orbit plasma environment. Analytical and numerical models of this arcing phenomenon on conventional solar cells have been developed which show excellent agreement with experimental data. With an understanding of a mechanism for arcing, it is possible to determine methods of arc rate mitigation and to predict arc rates for experiments. Using the previously developed models, it was determined that the arcing rate can be decreased by the following means: (1) increasing the interconnector work function; (2) increasing the thickness of the coverglass and adhesive; (3) decreasing the secondary electron yield of the coverglass and adhesive; (4) decreasing the ratio of the coverglass/adhesive dielectric constants; and (5) overhanging the coverglass. Of these, methods (4) and (5) show the most promise in reducing or even eliminating arcing. In addition, arcing rates were predicted for the high voltage biased arrays of the Air Force's Photovoltaic and Space Power Plus Diagnostics experiment (PASP Plus) and NASA's Solar Array Module Plasma Interactions Experiment (SAMPIE). These predictions provide both expectations for the missions and a means to test the numerical and analytical models in the space environment for different solar cell technologies. Finally, a numerical model of the arc initiation process was also developed for wrap-through-contact cells, but experimental data is not available for comparison. DTIC

A new Potential Fields approach to the robotic path planning problem is proposed and implemented. Our approach, which is based on one originally proposed by Munger, computes an incremental joint vector based upon attraction to a goal and repulsion from obstacles. By repetitively adding and computing these 'steps', it is hoped (but not guaranteed) that the robot will reach its goal. An attractive force exerted by the goal is found by solving for the the minimum norm solution to the linear Jacobian equation. A repulsive force between obstacles and the robot's links is used to avoid collisions. Its magnitude is inversely proportional to the distance. Together, these forces make the goal the global minimum potential point, but local minima can stop the robot from ever reaching that point. Our approach improves on a basic, potential field paradigm developed by Munger by using an active, adaptive field - what we will call a 'flexible' potential field. Active fields are stronger when objects move towards one another and weaker when they move apart. An adaptive field's strength is individually tailored to be just strong enough to avoid any collision. In addition to the local planner, a global planning algorithm helps the planner to avoid local field minima by providing subgoals. These subgoals are based on the obstacles which caused the local planner to fail. A best-first search algorithm A* is used for graph search. Author (revised)

A GUIDANCE AND NAVIGATION SYSTEM FOR TWO SPACECRAFT RENDEZVOUS IN TRANSLUNAR HALO ORBIT Ph.D. Thesis
Brian L. Jones May 1993 189 p
(AD-A267498; AFIT/CI/CIA-93-011D) Avail: CASI HC A09/MF A02

This research considers the design of a representative end-to-end guidance and navigation system for the terminal phase rendezvous of two spacecraft in the circular restricted three-body problem. It assumes the target vehicle is in a small radius translunar halo orbit; the target vehicle remains passive with respect to the rendezvous profile. The chaser vehicle is in an independent small radius translunar halo orbit and executes all rendezvous maneuvers. First, the halo orbit guidance problem is formulated in the frequency-domain from which an output feedback guidance law is developed using H2 control theory. Linear simulation results validate the guidance law and provide data which quantify the effect of control inputs, noise characteristics and halo orbit characteristics on the steady state halo orbit station-keeping costs. Secondly, a two spacecraft terminal phase rendezvous targeting law is derived; nonlinear simulation results validate the targeting law. DTIC

DETECTING SMALL DEBRIS USING A GROUND-BASED PHOTON COUNTING DETECTOR
C. Ho, W. C. Priedhorsky, and M. H. Baron 1993 10 p Presented at the Society of Photo-Optical Instrumentation Engineers (SPIE) OE/Aerospace Science and Sensing Meeting, Orlando, FL, 11-16 Apr. 1993
(Contract W-7405-eng-36)
(DE93-012623; LA-UR-93-1199; CONF-930445-10) Avail: CASI HC A02/MF A01

We describe a sensitive technique for detecting small space debris that exploits a fast photon-counting imager. Microchannel plate detectors using crossed delay-line readout can achieve a resolution of 2048 x 2048 spatial pixels and a maximum count rate of about 10(sup 6) photons per second. A baseline debris-tracking system might couple this detector to a 16-cm aperture telescope. The detector yields x, y, and time information for each detected photon. When visualized in (x, y, t) space, photons from a fast-moving orbital object appear on a straight line. They can be distinguished from diffuse background photons, randomly scattered in the space, and star photons, which fall on a line with sidereal velocity. By searching for this unique signature, we can detect and track small debris objects. At dawn and dusk, a spherical object of 1.3 cm diameter at 400 km will reflect sunlight for an apparent magnitude of V approximately = 16. The baseline system would detect about 16 photons from this object as it crosses a 1 degree field of view in about 1 second. The line in (x, y, t) space will be significant in a diffuse background of approximately 10(sup 6) photons. We discuss the data processing scheme and line detection algorithm. The advantages of this technique are that one can (1) detect cm-size debris objects with a small telescope, and (2) detect debris moving with any direction and velocity. In this paper, we describe the progress in the development of detector and data acquisition system, the preparation for a field test for such a system, and the development and optimization of the data analysis algorithm. Detection sensitivity would currently be constrained by the capability of the data acquisition and the data processing systems, but further improvements could alleviate these bottlenecks. DOE

Papers presented at a symposium to assess the status of research in photon detectors and to define a policy to achieve coherence in European detector research are presented. A photon detector is the heart of many space experiments; its characteristics and performance determine the size of the photon collection area and, consequently, directly influence the size and cost of the spacecraft. Given the access to technology previously classified, new perspectives are opened for photon detection in some ranges of the electromagnetic spectrum, particularly in the infrared and at submillimeter wavelengths. For individual titles, see N94-15026 through N94-15103.

A new generation of astrophysical gamma ray spectrometers employing germanium solid state detectors for precise energy measurement are currently being planned for spaceflight in the late 1990's and the early 21st century. Because the observations of weak celestial sources are carried out in an intense radiation environment, the key objective of instrument design is to find ways to reduce the background. The current state of the knowledge in this field is reviewed and the new hardware techniques under design and test are discussed. Many of these techniques have already been flight tested on balloon platforms. Recent results from some of these tests are presented. By carefully applying these techniques it should be possible to achieve sensitivities that are factors of 3 to 10 better than would be obtained for a conventional instrument of similar weight. ESA

Copyright Avail: CASI HC A02/MF A04

Microcalorimeters operating at cryogenic temperatures can be excellent X-ray spectrometers. They simultaneously offer very high spectral resolving power and high efficiency. These attributes are important for X-ray astronomy where most sources have low fluxes and where high spectral resolution is essential for understanding the physics of the emitting regions. The principles of operation of these detectors, limits to their sensitivity, design considerations, techniques of fabrication, and their performance as X-ray spectrometers, are reviewed. ESA

Considerable theoretical and experimental effort is being devoted to the development of superconducting tunnel junction X-ray photon counting detectors, with the goal of providing good quantum efficiency combined with high energy resolution. The fundamental physical processes underlying the use of such detectors (the partial destruction of the superconducting state leading to free charge carriers which can be detected through quantum mechanical tunneling at the junctions) are equally applicable at longer wavelengths. Optical photon counting should be possible using an array of closely packed junctions, or with an array of widely spaced junctions fabricated on a superconducting substrate of higher energy gap, employing the principle of quasi-particle trapping. Such a device should combine most of the advantages of CCD's (Charge Coupled Devices) and present photon counting systems; as a specific example, the combination of Al junctions with a Nb or Sn substrate provides the basis for a large area detector with very high sensitivity to individual optical and UV photons, high intrinsic time resolution, and moderate energy resolution. Some key astronomical applications of such a device are noted. ESA

The results of missions such as SIGMA and CGRO have convincingly demonstrated the need for fine spectroscopy and imaging in high energy astronomy. A possible answer to these requirements could be offered by Position Sensitive Detectors (PSD) based on modular arrays of Cadmium Telluride (CdTe) micro-spectrometers. CdTe is a room temperature compound semiconductor with high Z that can be formed into small devices acting as X and gamma ray spectrometers. PSD's based on CdTe would offer fine intrinsic spatial resolution (down to a few millimeters), good spectroscopic performance (less than 2% FWHM energy resolution at 511 keV) and high efficiency in the 10 keV to 5 MeV range. Experimental results obtained on CdTe micro-detectors with different geometrical shapes and size and on a sample of 5 by 5 units packed in a bidimensional array are presented. A design for assembling CdTe units in arrays of large detection area is suggested together with an evaluation of the achievable efficiency. ESA

An investigation of the LEPC (Low Energy Proportional Counter) is presented. A set of four imaging Microstrip Proportional Counters (MSPC) are to be provided as part of XSPECT, a contribution to the SODART telescopes. A High EPC (HEPC) and an LEPC will be provided for each of the SODART telescopes. The design is fixed and a prototype of LEPC is under construction. The properties of this detector are described. The detector has an excellent energy resolution of delta(E)(sub FWHM) = 0.33 (E/1 keV)(exp 1/2) keV. The inherent position resolution is less than 0.2 mm around 6 keV, and positional nonlinearities are less than 0.1 mm. The measured point spread function shows the capability for studying weak objects in the vicinity of strong ones. The gas gain is independent of position to better than 0.5 percent. The efficiency of charged particle rejection was measured. ESA

SUPERCONDUCTIVE X RAY PHOTON DETECTORS **c76**

P. A. J. deKorte *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 41-50 Sponsored by Netherlands Technology Foundation (For primary document see N94-15025 03-19)

Copyright Avail: CASI HC A02/MF A04

The status and developments in the area of superconductive photon detectors are reviewed with emphasis on superconductive tunnel junctions. An introduction to the basics of superconductive tunnel junctions for radiation is given together with the requirements on the read out electronics. Special attention is devoted to the influence of the various quasi-particle and phonon loss processes on the detector performance. The process of quasi-particle trapping, depending on the proximity effect, and the results obtained in the various experimental structures are addressed. This process also plays a central role in the read out of absorbers of a size substantially larger than the junctions themselves. Results of another way to increase detector size by the use of detector arrays are presented. ESA

The operational principles of superheated superconducting spheres are reviewed, and results of significance to their application in radiation detection are discussed. Metastable superconductors are found in either intrinsic or geometric states, naively characterized by microspheres and strips, respectively. With spheres, prototype matrix detectors have been built and provide the basis for potential imaging systems as well as specific particle detection systems. Recent results demonstrate that with rather large microspheres not selected in size, energy resolution can be achieved. Strips, recently studied with an induction readout technique, indicate a possible new form of detector with an enhanced capacity for energy resolution. ESA

The Reflection Grating Spectrometer (RGS) on ESA's X-ray Multi Mirror mission (XMM) will perform spectroscopy in the energy range of 0.3 to 2.5 keV. For optimum photon detection efficiency, the RGS will be equipped with fully depleted, back illuminated large area CCD's (Charge Coupled Devices) as detectors. The backside accumulation layer is produced by ion implantation and subsequent pulsed laser annealing and should not be thicker than 0.05 micrometers. So far, the CCD development program has resulted in a large area CCD with good performance with respect to read noise, charge transfer efficiency, and radiation hardening. Back illuminated CCD's have been fabricated with very shallow activated p+ layers (0.06 micrometers, from spreading resistance profiles). X-ray measurements, however, indicate that there is a 0.22 micrometer thick layer with charge collection less than unity. This may be due to a layer of implanted boron and associated lattice damage, which is left unanealed. Anodic etching,

ultralow energy implantation, and gas immersed laser doping are being studied as improvements and alternatives. ESA

A thinned, backside illuminated, two dimensional Charge Coupled Device (CCD) realized for incorporation into an image intensifier is reported. The detection of electrons of moderate energy (5 to 15 keV) by means of a CCD requires backside irradiation of devices whose sensitive region is thinned down to about 10 micrometers, such that the electrons are absorbed in the sensitive volume of the CCD. After thinning and packaging, the CCD's are subjected to a high temperature vacuum bake-out cycle, which poses severe requirements on both the die and wire bonding. The CCD's are finally incorporated into the image intensifier. ESA

There has been significant progress over the last few years in the development of technologies for microchannel plate imaging detectors in the Ultraviolet (UV). Areas where significant developments have occurred include enhancements of quantum detection efficiency through improved photocathodes, advances in microchannel plate performance characteristics, and development of high performance image readout techniques. The current developments in these areas are summarized, with their applications in astrophysical instrumentation. ESA

Open window Microchannel Plates (MCP's) are currently the detectors of choice for space astronomy in the Extreme Ultraviolet (EUV) and Far Ultraviolet (FUV) bands. MCP's are also commonly used in soft X-ray astronomy and, in sealed tubes, for optical photon counting. Work in a number of important development areas is described: MCP and MCP image readout operation at high count rates; the testing of 'low noise' MCP's fabricated from radioisotope free lead glass; and the construction and operation of large format (approximately 100 sq cm) channel plate detectors. The effects of in vacuo contaminants on an MCP bearing a CsI photocathode are also discussed. ESA

The MIC (Microchannel plate Intensified CCD (Charge Coupled Device)) detector is an advanced performance Micro Channel Plate (MCP) intensified CCD photon counting detector developed for high resolution, high dynamic range, astronomical applications. The heart of the detector is an MCP intensifier developed specifically for photon counting applications. The maximum detector format is 3072 by 2304 pixels. The measured resolution of the detector system is 18 micrometers FWHM at 490 nm. The detector is linear to approximately 1,000,000 events/detector area/sec on a flat field and linear to count rates up to 200 events/object/s on star images. Two versions of the system have been developed. The first for ground based astronomical applications based around a 40 mm diameter intensifier, was proven in trials at a number of large optical telescopes. The second, specifically for the ESA X-Ray Multi Mirror Mission (XMM), where the MIC has been accepted as the blue detector for the incorporated Optical Monitor (OM). For the XMM-OM, the system is based around a 25 mm diameter intensifier. At present, under development, is a 75 mm diameter version of the detector which will have a maximum format of 6144 by 4608 pixels. Details of the MIC detector and its performance are presented. ESA

The current developmental status and future potential of a promising hard X-ray and gamma ray detector are presented: the high pressure xenon gas scintillation imaging drift chamber. A scheme for reading out the scintillation light waveshifting fibers, which allows operation at pressures at least as high as 20 atmospheres, is used. This technique combines excellent spatial resolution (approximately 200 rms allowing 1.5 arcminute mapping resolution), very good energy resolution (within a factor of three of Ge detectors), good time resolution (approximately 100 ns), and extremely high sensitivity because of excellent background rejection capabilities; it also offers possibilities for extrapolation to large area detectors. Results from tests with a prototype chamber are presented. The design of a scientific instrument for a balloon flight planned in 1995 is described. This instrument, the Scintillation Imaging Gas filled Hard X-ray Telescope (SIGHT), is optimized for detecting 30 to 300 keV X-rays. It has an active area of 1140 sq cm, with a stopping power of between 2.0 and 2.7 g/sq cm of xenon at 20 atmospheres. Possible future evolutionary tracks of the technology leading to innovative satellite applications are discussed. ESA

The development of the 2048 by 2048 CCD (Charge Coupled Device) for a second generation space telescope instrument has resulted in devices with very few defects, dark currents of less than 12 electrons/pixel/hour at -80 deg, readout noise levels of less than 4 electrons rms, and excellent charge transfer efficiency at signal levels of less than 10 electrons. A second generation of devices that capitalize on these characteristics have been produced and are currently in test. Faster frame transfer devices that preserve these characteristics have been designed that include tridirectional taps in the serial register. The state of the art in CCD's as photon counting detectors is reviewed. ESA

The detection of faint electromagnetic radiation in space astronomy

and astrophysics requires very low temperatures to improve the signal to noise ratio of the very sensitive detectors in order to reduce the electronic noise of the detector amplifiers and finally to suppress the self emission of infrared radiation of the telescope itself. To provide such a cryogenic environment in space, both open and closed loop cooling systems using different cryogens are in use, thereby covering the whole temperature range from about 80K down to 1.8K. Future applications such as highly sensitive bolometers or SQUID's will ask for temperatures down to the subKelvin range. Such temperatures can be achieved by sophisticated low temperature cooling stages. Cryogenic cooling in space basically relies on the same cooling principles as in the laboratory. However the systems in general have to be specifically designed and new components have to be developed to match the cryogenic infrastructure to the specific demands of the optical instrument, the requirements from the satellite and the constraints imposed by the space environment. The demonstration of Visible Light Photon Counters (VLPCs) with a counting quantum efficiency of 60% is reported. A quantum efficiency in excess of 85% should be achievable with optimization. With such high photon detection efficiencies, the VLPC can have many applications in astronomy. Performance characteristics of this type of device are described and compared with other types of existing photon counters. Present devices operate best at a temperature of 6 to 7K. Due to the high and fast internal gain in the VLPC, the signal from a single detected photon is well above noise and can be monitored through simple readout circuitry. Compact multichannel cassettes which provide convenient optical inputs to line arrays of VLPCs and ease electrical readout from the arrays were designed. By inserting these cassettes into an efficient cryostat of simple design, the cassette could be cooled down rapidly to operating temperatures to evaluate VLPCs for various applications. Operation of the cassette and cryostat is described. ESA

The performances, advantages, and disadvantages of three detector technologies, which have produced devices of interest to astronomy and other scientific users, are compared: platinum silicide (PtSi), mercury cadmium telluride (MCT), and indium antimonide (InSb). All high performance arrays use a Source Follower per Detector (SFD) type of multiplexer readout because CCDs (Charge Coupled Devices) do not perform well at low operating temperatures. In addition, hybrid indium bump technology is used by all arrays for fabrication, yield, and performance reasons. The evolution of the present focal planes and where the technology is headed are discussed, covering the operation of the various technologies, and data on the performance of several of the new 256 by 256 focal planes is presented. Evaluation procedures used for astronomy applications and techniques for low noise operation are also discussed. The future trends in even larger focal planes and the requirements for the next generation of arrays are discussed. ESA

Doped silicon and germanium are used as extrinisic photoconductors for infrared astronomy from ground based, balloon and airborne observatories, and from space platforms. The detectors of the Infrared Space Observatory (ISO) will be capable of observing at the sensitivity limits imposed by natural sky background radiation. For the first time, ISO will use stressed Ge:Ga detectors on a satellite covering the wavelength range out to 240 micrometers. Preflight testing has shown that ISO's calibration will have to correct high energy radiation effects and delayed flux response of detectors. For future far infrared projects, these problems might be solved by blocked impurityband detectors. Several other difficulties in today's detector assembly production and readout technology also deserve improvements. ESA

NONSTATIONARY BEHAVIOUR OF LOW BACKGROUND PHOTON DETECTORS c35

B. I. Fouks *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 167-174 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A02/MF A04

Principles and results of the theory of nonstationary processes in extrinsic detectors are presented. The low resistive detector contacts, being ohmic during DC flowing, are well injecting extra carriers during flowing of AC even if the AC changes are very slow. At a low temperature and background, a free carrier charge does not limit AC value and the latter is confined by contact nonstationary injection ability. As a result, the current response on an illumination change is the long term one; it depends on the background value and contact parameter; it is completed by the long term oscillations. The theory explains all photoresponse peculiarities, including incomprehensible ones before. It describes well any nonstationary processes in various high resistivity semiconductors. The data of a number of extrinsic detector arrays are presented. ESA

Copyright Avail: CASI HC A01/MF A04

A 1536 pixels butted array consisting of three truly linear CCD (Charge Coupled Device) submodules was developed for infrared imaging. The pixel gap at the butting edges is nominally one and maximum two pixels and the alignment accuracy is better than 5 micrometers within the detector plane and better than 50 micrometers in the Z direction. Schottky barrier sensors were used as IR detectors incorporating three different silicides working in the front-side illumination mode. The main differences between these silicides are the cut-off wavelength and the operating temperature. CoSi2 and NiSi show a cut-off wavelength of about 2.8 micrometers allowing an operating temperature of 150 K and passive cooling, whereas PtSi has a cut-off wavelength of about 6 micrometers working at 77 K. All three devices present a good photoresponse uniformity along the sensor row and also a good noise behavior. ESA

N94-15051# Philips Components Ltd., Southampton (England).
ADVANCED HIGH PERFORMANCE CdHgTe MULTIPLEXED ARRAYS **c76**

I. M. Baker, D. E. Charlton, C. Arthurs, and G. Crimes *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 181-185 Sponsored by Ministry of Defence (For primary document see N94-15025 03-19)

The use of SIS tunnel junctions as mixers in submillimeterwave heterodyne receivers provides the best possible sensitivities up to frequencies as high as 500 GHz. Several laboratories have now demonstrated that SIS receivers in that regime have better sensitivity than the more traditional Schottky instruments. In addition, the low level of local oscillator power required for SIS receivers makes further development especially attractive for the high frequencies, possibly up into the THz regime. A fabrication process of niobium tunnel junctions and their application in waveguide mixers for the 330 to 380 GHz as well as the 410 to 490 GHz bands are described. The use of SIS detectors in planar antennas is especially promising for applications in imaging array receivers. The use of planar double dipole antennas in combination with ellipsoidal lenses is described. ESA

Yngvesson (Massachusetts Univ., Amherst.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 201-206 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A02/MF A04

The urgent need in radio astronomy for low noise heterodyne receivers for frequencies above about 500 GHz is discussed. It is not certain that mixers based on superconducting quasiparticle tunneling (SIS mixers) may turn out to be the answer to this need. In order to try to find an alternative way for realizing low noise heterodyne receivers for submillimeter waves, so called hot electron bolometric effects for mixing are now being investigated. Two basically different approaches are tried, one based on semiconductors and one on superconductors. Both methods are discussed. Experimental evidence so far shows that with semiconductor heterostructures, two Dimensional Gas (2DEG) 18 dB conversion loss has

been obtained, and of the order of 5 dB using superconductors. Noise has as yet not been experimentally determined. Calculations suggest that the 2DEG mixers may offer of the order of 500 K (or less) DSB at 1 THz, while for superconductor devices still lower noise temperatures are predicted. ESA

The theory of operation of submm/FIR bolometers and their technology are described. Bolometers are detectors that work by recording the temperature rise due to the absorption of radiation with the aid of a resistance thermometer. Photons of any wavelength can be detected as long as an efficient absorbing structure for that wavelength can be designed. In fact, even particle radiation can be detected by the same mechanism. While thoughout much of the electromagnetic spectrum other types of detectors are superior, bolometers are still the most sensitive detectors for continuum radiation in the mm/submm range. Therefore, all large ground based mm/submm telescopes are equipped with bolometers for continuum studies. In principle, the performance of a bolometer can be improved without limits by lowering the operating temperature. At temperatures below 300 mK, bolometers have the potential to operate near the fundamental background limit in most environments. Combining them into arrays is relatively easy because of the basic simplicity of the detectors and the associated electronics. Therefore bolometers seem to be able to stand up to the challenge of competing detector technologies in the near future. ESA

Remarks on posters and oral presentations addressing the application of infrared detectors and coolers as space instrumentation are presented. Achievements and status in this area are summarized: a comparison of the IRAS (Infrared Astronomy Satellite) mission with the ISO (Infrared Space Observatory); transient effects in extrinsic photoconductors; block impurity band detectors; and bolometers. Future developments are discussed: coverage of the far IR by even larger arrays; cooling of the new generation IR mission by closed cycle coolers; and definition of the next mission. The progress in IR astronomy is outlined in conclusion. ESA

A long term program for the research of the aurora and the interaction of the solar wind plasma with the Earth's magnetic field and atmosphere is discussed. The Freja satellite is part of that program. Among several other experiments, the Freja satellite carries two UV sensitive cameras which will make images of the aurora. The cameras contain special types of UV image intensifiers. The satellite was launched on 5 Oct. 1992 and first images have already been received. ESA

The recent discoveries and excitement generated by EGRET (Energetic Gamma Ray Experiment Telescope) (presently operating on CGRO (Compton Gamma Ray Observatory)) has prompted an investigation into modern technologies ultimately leading to the next generation space based gamma ray telescope. The goal is to design a detector that would increase the data acquisition rate by almost two orders of magnitude beyond EGRET, while at the same time improving on the angular resolution, the energy measurement of reconstructed gamma rays and the triggering capability of the instrument. The proposed GLAST (Gamma Ray Large Area Silicon Telescope) instrument is based on silicon particle detectors that offer the advantages of no consumables, no gas volume, robust (versus fragile), long lived, and self triggering. The GLAST detector is roughly modeled after EGRET in that a tracking module precedes a calorimeter. The GLAST tracker has planes of cross strip (x, y) 300 micrometer match silicon detectors coupled to a thin radiator to measure the coordinates of converted electron-positron pairs. An angular resolution of 0.1 deg at high energy is possible (the low energy angular resolution 100 MeV would be about 2 deg, limited by multiple scattering). The increased depth of the GLAST calorimeter over EGRET's extends the energy range to about 300 GeV. ESA

A TEST FACILITY TO CALIBRATE EUV DETECTORS **c09**
Giovanni Bonanno, Giampiero Naletto (Padua Univ., Italy.), and Giuseppe Tondello (Padua Univ., Italy.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 233-236 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

A test facility to calibrate detectors in the ultraviolet region between 300 A and 2500 A is described. It consists of a vacuum normal incidence Johnson-Onaka monochromator with a set of interchangeable gratings and several UV lamps to optimally cover the whole spectral range. A pair of NIST calibrated photodiodes allows an absolute measurement of the photon flux outcoming from the monochromator, and thus it is possible to evaluate

the quantum efficiency of the detectors under test. Moreover, other characteristic parameters of UV detectors can be evaluated, like for example the spatial resolution and the uniformity response. The results of the quantum efficiency measurements of an EEV ion implanted CCD (Charge Coupled Device) are shown. The possible improvements necessary to optimize this test facility are discussed. THE GRAZING INCIDENCE DETECTORS FOR THE SOHO CORONAL DIAGNOSTIC SPECTROMETER
A. A. Breeveld and P. D. Thomas *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 237-241 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

The Grazing Incidence Spectrometer (GIS) forms part of the Coronal Diagnostic Spectrometer (CDS) on SOHO (Solar and Heliospheric Observatory). Ultraviolet light is focused onto a Rowland circle, where four detectors image the spectra of chosen wavelength ranges, between 15 and 80 nm. Since the detectors are tangential to the circle, the incoming light meets the surfaces at grazing incidence. The detector design is a microchannel plate 'z-stack', backed by a SPAN anode, position sensitive in one dimension. The detectors are required to work at a high speed (100,000 counts/sec) and to have a resolution of better than 47 micrometers over the 50 mm length. The design, construction and performance testing of the GIS detectors and associated electronics are examined in the context of the resolution and throughout requirements. The special requirements needed for a space application and for running an anode at high voltage are described. ESA

THE TAUVEX EXPERIMENT
Noah Brosch (Tel-Aviv Univ., Israel.), Amotz Shemi (Tel-Aviv Univ., Israel.), Jeremy Topaz (Electro-Optical Industries Ltd., Rehovot, Israel.), and Ofer Braun (Electro-Optical Industries Ltd., Rehovot, Israel.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 243-247 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

The TAUVEX (Tel Aviv University UV Explorer) payload will be launched in 1995 onboard the spectrum X-gamma spacecraft, as part of the SODART (Soviet-Danish X-ray Telescope) high energy experiment. It consists of three 20 cm diameter coaligned telescopes imaging the same 0 deg .9 diameter sky area onto photon counting detectors in the 1400 to 2800 A band. The expected lifetime of the platform of at least three years will permit coverage of approximately 8% of the sky with a sensitivity of approximately 21 mag for point sources. The entire design of the payload depends strongly on the availability of imaging photon counting detectors in the desired spectral range. ESA

DISCRETE CMT INFRARED DETECTORS FOR SPACE APPLICATION, FROM ISSR TO SECOND GENERATION METEOSAT AND MIPAS
D. E. Charlton, L. G. Moore, and W. I. McMillan (MATRA Marconi Space, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 249-254 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A02/MF A04

Design constraints, electronic requirements, and housing requirements for space application of CMT detectors are described. The CMT detector was used in the thermal band of the Infrared Spin Scan Radiometer (ISSR) flown on the U.S. Synchronous Meteorological Satellite in the 1970's. Space application calls for high performance, often in low background flux, and with a diversity of wavelength. This presents design constraints often more demanding than terrestrial applications. However, there is considerable freedom to optimize temperature of operation. Verification of performance requirements calls for both practical demonstrations and modeling. CMT photodiodes are generally best at shorter wavelengths, while photoconductive detectors are generally better at long wavelengths. The diffference in approach and the design trades required in detectors for space application are compared with terrestrial thermal imaging. This is illustrated by consideration of the design trades for the MIPAS (Michelson Interferometer for Passive Atmospheric Sounding) detectors and preamplifiers. ESA

Swinyard (Rutherford Appleton Lab., Chilton, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 255-260 Sponsored in part by Science Research Council (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A02/MF A04

The ISO (Infrared Space Observatory) Long Wavelength Spectrometer (LWS) uses an array of ten doped germanium photoconductors to cover the wavelength range 45 to 200 micrometers. The performance of the detectors was characterized, optimized, and calibrated, both individually and in the flight instrument. The detector test techniques and calibration methods are described and results for the spectral response, dark current, responsivity, and noise equivalent power are presented. The dependence of these parameters on operating conditions was explored and optimum values established for the flight instrument. Calibration of the flight instrument demonstrated that the sensitivity of the LWS is within specifications. ESA

Swinyard (Rutherford Appleton Lab., Chilton, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 261-264 Sponsored in part by Science Research Council (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

The ISO (Infrared Space Observatory) Long Wavelength Spectrometer (LWS) uses an array of ten doped Ge photoconductors to cover the wavelength range 45 to 200 micrometers. Under the low background conditions appropriate to the LWS, these devices are know to exhibit a number of memory effects, such as spontaneous spiking at high signal levels and slow relaxation after a step change in illumination. This type of nonlinear behavior can cause degradation of the excellent instantaneous sensitivity of the LWS detectors, and other calibration problems. These effects were studied and the implications of operation and calibration of the LWS are considered. ESA

Takada (Tsukuba Univ., Ibaraki, Japan.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 265-268 Sponsored by CNR and ETL (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

High quality Nb based Superconducting Josephson Tunnel Junctions (SJTJ) are promising devices as detectors of nuclear radiation because of the low energy threshold, fast response, and good thermal cyclability. The samples utilized were fabricated with underlayer technique and a self aligned insulation process in silicon substrates. A 5 by 5 sq mm chip containing as many as 240 SJTJ's was designed with various junction configurations oriented toward energy and time sensitive detection. The chip was irradiated with alpha particles from an Am-241 source located 5 mm above the junction and separated by a mechanically controlled shutter. Pulse height and risetime spectra of both 'island' type and series connected SJTJ's are reported. Signals generated by nuclear radiation were observed at temperatures up to 2K, where a reduction of the collected charge occurs because of the enhancement of the recombination rate. ESA

The STIS (Space Telescope Imaging Spectrograph) is a second generation Hubble instrument scheduled to fly in 1997. Through a variety of modes, the instrument will provide spectral resolutions from R approximately 50 in the objective spectroscopy mode to 100,000 in the high resolution echelle mode in the wavelength region from 115 to 1000 nm. In the UV the instrument employs two MAMA (Multimode Anode Microchannel plate Arrays) 1024 by 1024 pixel detectors, which provide high DQE (Detective Quantum Efficiency), and good dynamic range and resolution. The current progress and performance of these detectors are reported, illustrating that the technology is mature and that the performance is very close to flight requirements. ESA

AN ADIABATIC DEMAGNETISATION REFRIGERATOR WITH A MECHANICAL PRE-COOLER FOR SPACE APPLICATIONS

I. J. Davenport, A. Smith, I. Hepburn (London Univ., England.), P. A. R. Ade (London Univ., England.), and T. J. Sumner (Imperial Coll. of Science and Technology, London, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 275-279 Sponsored in part by Science Research Council (For primary document see N94-15025 03-19)

Copyright Avail: CASI HC A01/MF A04

An Adiabatic Demagnetization Refrigerator (ADR) suitable for use in space would have applications in the fields of mm/submm and x-ray astronomy. Since ADR's operate in the absence of gravity without the need for highly complex modifications from established laboratory designs, they could offer a considerable advantage over He-3 refrigerators. The concept of an ADR backed by a mechanical pre-cooler is evaluated. Either a second ADR or a recycling Helium bath is used between the ADR and the mechanical cooler. This has the potential for both high reliability and very long operations. A system design which is related to the present development status of mechanical coolers is presented. The performance of such a system is evaluated. The operational parameters addressed include: achievable temperature and stability; hold and recycle times; and residual magnetic field strength. ESA

Results of an evaluation of silicon P-Intrinsic-N (PIN) photodiodes and Avalanche Photodiodes (APD) for the direct detection of soft x rays from 1 to 20 keV and for the detection of scintillation light output from CsI(Tl) for higher x ray energies (30 to 1000 keV) are presented. About one keV resolution was achieved at room temperature for both the PIN and APD detectors for soft x rays (1 to 20 keV). Commercially available, low power (18 mV), low noise, hybrid preamplifiers, were used. These photodiodes were also coupled to CsI(Tl) scintillator and obtained about 6 resolution at 662 keV. The photodiode frequency response matches well with the emission spectrum of the CsI(Tl) scintillator providing good spectral resolution and a higher signal than NaI(Tl) when viewed by conventional photomultipliers. A PIN-CsI(Tl) combination provides a low energy threshold of around 60 keV while for the APD-CsI(Tl) it is 15 keV. ESA

IONISING RADIATION-INDUCED EFFECTS IN DOPED GERMANIUM FIR PHOTOCONDUCTORS **c76**
M. C. Price, M. J. Griffin, S. E. Church, A. G. Murray, and P. A. R. Ade *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 309-312 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

Bulk Ge:Be and Ge:Ga photoconductive devices with a typical crystal size of about 1 mm, are currently the most sensitive detectors for FIR satellite instruments in the wavelength range 40 to 200 micrometers. Due to their high sensitivity and relatively large volume, the performance of these detectors is strongly influenced by ionizing radiation in space. Individual absorption events cause glitches in the data stream which must be rejected; and changes in detector dark current, responsivity and noise arise due to the accumulated ionizing radiation exposure. It is essential to characterize and minimize these effects in order to attain the best overall performance of satellite-borne detectors. Radiation tests in Ge:Be and Ge:Ga (stressed and unstressed) detectors for the ISO (Infrared Space Observatory) Long Wavelength Spectrometer (LWS), a low background FIR astronomical instrument, and SAFIRE (Spectroscopy of an Atmosphere using Far Infrared Emission), a higher background Earth looking instrument, were carried out. The effects of ionizing radiation on the performance parameters of the different detectors types are described and discussed. The effectiveness of curing the detectors by bias boosting is considered, and the implications of the ionizing environment for operation of FIR satellite instruments are outlined. ESA

The new generation of photon detectors for satellite based mm/submm and X-ray astronomical observations require cooling to temperatures in the range 60 to 300 mK. At present Adiabatic Demagnetization Refrigeration (ADR) is the best proposed technique for producing these temperatures in orbit due to its inherent simplicity and gravity independent operation. For the efficient utilization of an ADR it is important to realize long operational times at base temperature with short recycle times. These criteria are dependent on several parameters; the required operating temperature, the cryogen bath temperature, the amount of heat leakage to the paramagnetic salt, the volume and type of salt and the maximum obtainable magnetic field. For space application these parameters are restricted by the limitations imposed on the physical size, the mass, the available electrical power and the cooling power available. The design considerations required in order to match these parameters are described and test data from a working laboratory system is presented. ESA

CCD'S ON HIGH RESISTIVITY BULK SILICON FOR X RAY SPECTROSCOPY ON XMM **c76**
A. D. Holland, M. J. L. Turner, A. A. Wells, and D. J. Burt (GEC Hirst Research Centre, Wembley, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 321-324 Sponsored by Science Research Council (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

CCD's (Charge Coupled Devices) were chosen as the X-ray imaging spectrometers on ESA's cornerstone mission XMM (X-ray astronomy Multi Mirror). The CCD's being developed for the nondispersive imaging spectrometer (EPIC), operating in the 0.1 to 15 keV band and which require high quantum efficiency with Fano limited energy resolution are described. The CCD's are manufactured on bulk silicon with resistivity greater than 8000 Omega cm. This produces a depletion depth approaching 90 micrometers which yields good X-ray spectroscopy with high efficiency (90 percent at 6.4 keV). The developments described are sufficient to satisfy the high energy requirements of the EPIC imaging spectrometer. ESA

A NEW DETECTOR CONCEPT FOR ENERGETIC AURORAL X RAY IMAGING
G. A. Johansen and J. Stadsnes *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 325-328 Sponsored by Royal Norwegian Council for Scientific and Industrial Research and Norwegian Research Council for Science and the Humanities (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

Energetic electrons being precipitated from the Earth's magnetosphere into the upper atmosphere in the auroral regions, emit bremsstrahlung X-rays. From a satellite an X-ray camera can be used for remote mapping of this electron precipitation. In connection with projects like Aurio (Auroral Imaging Observatory), selected for flight in ESA's polar platform program, it is desirable to develop new and better imaging detectors to cover especially the high energy range (about 10 to 150 keV). Scintillation crystals provide sufficient stopping efficiency at high X-ray energies. A scintillation readout device, the Electron bombarded silicon Diode Photo Multiplier Tube (EDPMT) is described with the first experimental results. Some ideas on how the EDPMT can be made position sensitive to be used together with a scintillating plate as a rugged and simple X-ray camera are presented. ESA

Superconducting Nb/AlOx/Nb tunnel junction detectors on bulk Si substrates show a spatially inhomogeneous detector response when part of the energy of an ionizing particle is deposited in the substrate. Nb/AlOx/Nb tunnel junctions with V(sub m) = 24 mV were prepared on 1 to 2 micrometer thick Si membranes. The spatial homogeneity of the response signal for the detection of 35 keV electrons improves significantly for junctions on Si membranes as compared to junctions on bulk silicon. The signal decay time for the membrane detector is about 450 microseconds at T = 5K, reducing the minimum energy (e) required to generate and count a single excess quasiparticle to (e) less than 6 meV. Constraints for the spectroscopy of X-rays with high energy resolution in superconducting tunnel junction detectors are discussed. ESA

The ISO (Infrared Space Observatory) Short Wavelength Spectrometer (SWS) employs four different types of detectors, which will all be operated at a low flux. Preliminary results of an extensive characterization of these detectors, both in the flight instrument and in a laboratory setup, are presented. In general, the performance of the instrument is as expected and quite low instrument noise equivalent powers are achieved (approximately 10 to the minus 17th power W/square root of Hz). However, the behavior of at least one of the detector types, Si:Sb, is troublesome. Characteristic features of this behavior are presented: long time transient response, memory effects, hook effects and excess noise. The Si:Sb transient responses can be described by two time constants. In contrast with the amplitude of the transient responses, these time constants depend only weakly on illumination power, temperature and bias voltage. This anomalous detector behavior implies specific designs of the observation strategies, which have to avoid 'flat-fielding' difficulties. ESA

The Absolute Radiometric Measurements in Space (ARMS) project proposes the development of a new primary radiometric standard for use in space traceable to the SI system of units. The standard, the Cryogenic Solar Absolute Radiometer (CSAR) will be capable of measuring the total irradiance of the Sun with an uncertainty of 0.01 percent, and a resolution of 0.001 percent, more than a factor ten improvement over existing instruments. ARMS was submitted to ESA in response to a call for opportunities for Columbus precursor flights and CSAR is currently on the provisional payload of Eureca 3. ESA

An outline of the Grazing Incidence detector Spectrometer (GIS) for the Soho (Solar and Heliospheric Laboratory) Coronal Diagnostic Spectrometer (CDS) is presented and the design of the transputer based data processor and control system, is described. The GIS uses four detector heads each having a microchannel plate EUV sensor with one dimensional progressive geometry readout. They are arranged around the Rowland circle of a grating and cover four separate wavelength ranges over 150 to 800 A. The sensor information is decoded to provide 2048 positions for each detector head which map directly as wavelength. The science information processing and the command and housekeeping system is described, including an appreciation of the important tradeoffs necessary for a practical design for space applications. 'First generation' superconducting tunnel junction X-ray detectors (characterized by a single tunnel junction in direct contact with its substrate, with totally external amplification) remain more than an order of magnitude away from their theoretical energy resolutions which are in the order of eV's. The difficulties that first generation devices are encountering are being attacked by a 'second generation' of superconducting X-ray detector designs including quasiparticle trapping configurations and Josephson junction arrays. A second generation design concept, the multilayered superconducting tunnel junction X-ray detector, consisting of tens to hundreds of tunnel junctions stacked on top of one another (a superlattice), is presented. Some of the possibilities of this engineered materials approach include the tuning of phonon transmission characteristics of the material, suppression of parasitic quasiparticle trapping and intrinsic amplification. The energy resolution of a conventional silicon spectrometer is limited by the noise associated with leakage currents and capacitance. The noise can be reduced by cooling and by using detectors which have a small capacitance. In principle, silicon devices using drift technology should in some respects be superior to CCD's (Charge Coupled Devices). Measurements were made on both position sensitive spectrometers and large area photodiodes at low temperatures. Timing resolutions of a few microseconds, position resolutions of the order a fraction of a millimeter, and FWHM energy resolutions of 1 keV at 20 keV were obtained for single photon events in a 1 sq cm detector. As scintillator readout devices the photodiodes give a resolution comparable with that of conventional diodes when coupled to CsI(Tl) at room temperature, and superior to that of conventional diodes when coupled to BGO at low temperature. A review of IR detection modules for space application with an emphasis on three new programs is presented. The first two belong to the spectrometry application and the third to lidar technology. The first program called Omega consists of arrays of detectors for Mars '94 spacecraft to be implemented in the Meudon Observatory (France) IR spectrometer, named Omega, with the purpose to observe mineralogy, water, ice and atmosphere in the IR spectrum. The flight models, each having two arrays and IR filters in a dedicated housing, are under development. The second consists of IR detectors for the IASI (Improved Atmospheric Sounding Infrared) instrument of which the aim is: IR observation of clouds for the Globsat program. The feasibility of long wavelength IR photoconductor with LPE HgCdTe material was studied. The last application is HF heterodyne detectors for lidar application (wind speed measurement projects). The instruments are laser wind sounder (wind speed lidar) and the purpose is the global change from tropics atmosphere in case of a satellite (or airborne) onboard instrument. A subsystem for heteorodyne detector including a high stability (100 kHz) CO2 laser at lambda = 9.11 micrometers and a HgCdTe photovoltaic detector T = 140 K fc = 1000 MHz, is under development. These two last instruments are candidates as payload to be integrated into the ESA polar platforms. ESA

Copyright Avail: CASI HC A01/MF A04

High sensitivity infrared detectors made from extrinsic semiconductors are of considerable importance for astronomical missions on satellites in Earth orbit. High energy radiation changes their sensitivity and their calibration. The photoconductors therefore necessitate onboard annealing and frequent recalibrations. Mid infrared diode lasers with low power dissipation are used for both applications, annealing with the stimulated, and recalibration with the spontaneous emission mode. ESA

REQUIREMENTS ON CCD-DETECTORS FOR GROUND-BASED AURORAL IMAGING **c89**

A. Steen and U. Braendstroem *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 379-382 (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

The aurora is a three dimensional time dependent signal with additional information in the spectral regime. The large dynamic range of the auroral signal raises rigorous requirements on the imaging detector. A new system for ground based auroral imaging, ALIS (Auroral Large Imaging System), is being constructed in the northern part of Sweden, using up to 14 stations with CCD (Charge Coupled Device) cameras. The stations are separated with about 50 km and are connected to a control center. Tomographic conversion techniques are applied to derive the three dimensional auroral signal. The key component of the ALIS system is the imaging detector. Unfortunately it is not possible to acquire an ideal auroral imaging detector; instead several compromises are necessary and shortcomings need to be overcome. The important aspects of the design of a ground based auroral imaging system are discussed. ESA

PERFORMANCE OF THE POSITION-SENSITIVE PROPORTIONAL COUNTERS OF THE YOHKOH BRAGG CRYSTAL SPECTROMETER

M. W. Trow *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 383-387 Sponsored by Science Research Council (For primary document see N94-15025 03-19)
Copyright Avail: CASI HC A01/MF A04

The position sensitive proportional counter used in the Bragg Crystal Spectrometer (BCS) on the Yohkoh spacecraft (formerly known as Solar-A) is described. The BCS provides time resolved spectra of solar flares in soft X-rays (2.4 to 7.0 keV) with improved sensitivity over previous studies. This sealed detector, filled with a Xe-Ar-CO2 gas mixture, uses thin (15 micrometers) anodes, and a backgammon cathode board to provide one dimensional imaging along the dispersion axis of the spectrometer. The performance and calibration procedures for the detectors are discussed, and the use of the calibrations in interpreting BCS data is illustrated. ESA

THE RUTHERFORD APPLETON LABORATORY PHOTON COUNTING DETECTOR **c35**

I. G. vanBreda, M. K. Carter (Rutherford Appleton Lab., Chilton, England.), B. E. Patchett (Rutherford Appleton Lab., Chilton, England.), and P. D. Read (Rutherford Appleton Lab., Chilton, England.) *In* ESA, Proceedings of an ESA Symposium on Photon Detectors for Space Instrumentation Dec. 1992 p 393-396 (For primary document see N94-15025 03-19)

Copyright Avail: CASI HC A01/MF A04

The Rutherford Appleton Laboratory Photon Counting Detector is a two dimensional area detector having a wide range of applications at optical, UV and X-ray wavelengths, both ground based and in space. It makes use of a microchannel plate intensifier and 'software centroiding' to derive the coordinates for photon events. The intensifier is coupled by means of a fiber optic taper either to a frame transfer CCD (Charge Coupled Device) or a CID camera running at video rates. Readout data frames are passed to a transputer array for analysis, where the event centroids are first calculated using an approximate numerical algorithm, then corrected using a lookup table. The current characteristics of the detector and some possible future developments are discussed. ESA

Copyright Avail: CASI HC A01/MF A04

The development of the cold readout electronics for the ISOPHOT focal plane experiment on the ISO (Infrared Space Observatory) is reported. For this low background application, custom designed highly sensitive integrating charge amplifiers are used for the readout of the extrinsic IR detectors. The use of CMOS circuits allows the multiplexing and readout of a large number of detectors at the detector temperature, with a very low power dissipation. The CMOS readout amplifier/multiplexer for deep cryogenic operation is discussed. The device is able to interface directly with extrinsic photoconductive detectors cooled down to the 1.8 to 10K range. In order to observe faint objects under low light level conditions the integration capacitor is 80 fF, featuring a saturation at 1 million charge carriers for an output voltage swing of 2 V and a noise level of 0.5 mV root mean square in nondestructive readout mode. With this circuit coupled to detectors with a responsivity of around 5 to 10 A/W, it is possible to reach noise equivalent power values of 10 to the minus 17th power W/square root of Hz. The multiplexer can be operated with only 10 wires for the supplies, and the clocking of the circuits. ESA

(Contract ESA-6044/84/NL/PB)

Copyright Avail: CASI HC A01/MF A04

A 1536 pixels butted array consisting of three CCD (Charge Coupled Device) modules with a truly linear sensor row and with a bilinear readout organization was developed for infrared imaging. The pixel gap at the butting edges is nominally 1 and maximum 2 pixels and the alignment accuracy is better than 5 micrometers within the detector plane and better than 50 micrometers in the Z direction. Photoconductive polycrystalline PbTe detectors were deposited directly on top of a CCD multiplexer circuit, resulting in most probably a lead salt detector array with the highest degree of integration, reported so far. The devices are operated in the 77 to 120K range and are showing a peak responsivity of 240 GV/J and a minimum noise equivalent power of 130 fW/square root of Hz. ESA

The ion implanted Si bolometer has unequaled performance as a high resolution X-ray detector. The superconducting tunnel junction detector has to date, been unable to provide such performance. A new form of Si bolometer using single crystal epitaxial growth to replace ion implantation for better power handling, good uniformity and low excess noise, is under development. The use of epitaxial growth allows the production of single crystal layers with a thickness of up to 40 micrometers with simultaneous doping from a secondary dopant gas stream. In addition, the layer can be capped with an undoped layer to minimize excess noise and further improve performance. ESA

EIGHTH INTERNATIONAL WORKSHOP ON LASER RANGING INSTRUMENTATION

John J. Degnan, comp. Washington Jun. 1993 741 p Workshop held in Annapolis, MD, 18-22 May 1992
(NASA-CP-3214; Rept-93B00079; NAS 1.55:3214) Avail: CASI HC A99/MF A06

The Eighth International Workshop for Laser Ranging Instrumentation was held in Annapolis, Maryland in May 1992, and was sponsored by the NASA Goddard Space Flight Center in Greenbelt, Maryland. The workshop is held once every 2 to 3 years under differing institutional sponsorship and provides a forum for participants to exchange information on the latest developments in satellite and lunar laser ranging hardware, software, science applications, and data analysis techniques. The satellite laser ranging (SLR) technique provides sub-centimeter precision range measurements to artificial satellites and the Moon. The data has application to a wide range of Earth and lunar science issues including precise orbit determination, terrestrial reference frames, geodesy, geodynamics, oceanography, time transfer, lunar dynamics, gravity and relativity. For individual titles, see N94-15553 through N94-15625.

LASER TRACKING FOR VERTICAL CONTROL **c36**

Peter Dunn (Hughes STX, Inc., Lanham, MD.), Mark Torrence (Hughes STX, Inc., Lanham, MD.), Erricos Pavlis (Maryland Univ., College Park.), Ron Kolenkiewicz, and David Smith *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 18 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

The Global Laser Tracking Network has provided LAGEOS ranging data of high accuracy since the first MERIT campaign in late 1983 and we can now resolve centimeter-level three dimensional positions of participating observatories at monthly intervals. In this analysis, the station height estimates have been considered separately from the horizontal components, and can be determined by the strongest stations with a formal standard error of 2 mm using eight years of continuous observations. The rate of change in the vertical can be resolved to a few mm/year, which is at the expected level of several geophysical effects. In comparing the behavior of the stations to that predicted by recent models of post-glacial rebound, we find no correlation in this very small effect. Particular attention must be applied to data and survey quality control when measuring the vertical component, and the survey observations are critical components of the geodynamic results. Seasonal patterns are observed in the heights of most stations, and the possibility of secular motion at the level of several millimeters per year cannot be excluded. Any such motion must be considered in the interpretation of horizontal inter-site measurements, and can help to identify mechanisms which can cause variations which occur linearly with time, seasonally, or abruptly. Avail: CASI HC A02/MF A06

Communications Research Laboratory (CRL) has been developing a laser time transfer system using a satellite laser ranging (SLR) system. We propose Japanese geodetic satellite 'AJISAI', launched in 1986 as a target satellite. The surface is covered not only with corner cube reflectors but also with mirrors. The mirrors are originally designed for observation of flushing solar light reflected by the separate mirrors while the satellite is spinning. In the experiment, synchronized laser pulses are transferred via specified mirror from one station to another while the satellite is up on the horizon to both stations. The system is based on the epoch timing ranging system with 40 ps ranging precision, connected together with UTC(CRL). Simulation study indicates that two stations at thousands of km distance from each other can be linked with signal strength of more than 10 photons and the distributed images of laser beam from AJISAI mirrors give many chances for two stations to link each other during a single AJISAI pass. Retro-reflector In Space for Advanced Earth Observation Satellite (ADEOS) and RendDezVous docking mission of Experimental Technology Satellite-7 (ETS-7) are briefly presented. Author (revised)

APPLICATIONS OF SLR **c36**

Bob E. Schutz *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 4 p (For primary document see N94-15552 03-19)
Avail: CASI HC A01/MF A06

Satellite Laser Ranging (SLR) has a rich history of development which began in the 1960s with 10 meter-level first generation systems. These systems evolved with order of magnitude improvements to the systems that now produce several millimeter single shot range precisions. What

began, in part, as an interesting application of the new laser technology has become an essential component of modern, precision space geodesy, which in turn enables contributions to a variety of science areas. Modern space geodesy is the beneficiary of technological developments which have enabled precision geodetic measurements. Aside from SLR and its closely related technique, Lunar Laser Ranging (LLR), Very Long Baseline Interferometry (VLBI) has made prominent science contributions also. In recent years, the Global Positioning System (GPS) has demonstrated a rapidly growing popularity as the result of demonstrated low cost with high precision instrumentation. Other modern techniques such as DORIS have demonstrated the ability to make significant science contributions; furthermore, PRARE can be expected to contribute in its own right. An appropriate question is 'why should several techniques be financially supported'? While there are several answers, I offer the opinion that, in consideration of the broad science areas that are the benefactors of space geodesy, no single technique can meet all the requirements and/or expectations of the science areas in which space geodesy contributes or has the potential for contributing. The more well-known science areas include plate tectonics, earthquake processes, Earth rotation/orientation, gravity (static and temporal), ocean circulation, land, and ice topography, to name a few applications. It is unfortunate that the modern space geodesy techniques are often viewed as competitive, but this view is usually encouraged by funding competition, especially in an era of growing needs but diminishing budgets. The techniques are, for the most part, complementary and the ability to reduce the data to geodetic parameters from several techniques promotes confidence in the geophysical interpretations. In the following sections, the current SLR applications are reviewed in the context of the other techniques. The strengths and limitations of SLR are reviewed and speculation about the future prospects are offered. Author

SATELLITE SIGNATURES IN SLR OBSERVATIONS **c36**
G. M. Appleby *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 14 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

We examine the evidence for the detection of satellite-dependent signatures in the laser range observations obtained by the UK single-photon Satellite Laser Ranging (SLR) System models of the expected observation distributions from Ajisai and Lageos are developed from the published satellite spread functions and from the characteristics of the SLR System and compared with the observations. The effects of varying return strengths are discussed using the models and by experimental observations of Ajisai, during which a range of return levels from single to multiple photons is achieved. The implications of these results for system-dependent center for mass corrections are discussed. Author (revised)

WORK AT GRAZ ON SATELLITE SIGNATURES **c18**
Georg Kirchner and Franz Koidl *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 8 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

The size and shape of the satellites retroreflector arrays have a major impact on the distribution and scatter of the return signal; this can be seen clearly when reaching sub-cm ranging accuracies and when using Single-Photon Detectors with single- or multi-photon returns; for other receiver systems (using MCP's), it should be checked also. As a consequence, the necessary center-of-mass correction for some satellites will differ, depending on the receiver systems. While this effect is not yet visible on small satellites or small retro-reflector arrays (like STARLETTE, ERS1), it can be in the order of centimeters on AJISAI or ETALON. Author (revised)

THE PRECISION OF TODAY'S SATELLITE LASER RANGING SYSTEMS
Peter J. Dunn, Mark H. Torrence, Van S. Hussen (Bendix Field Engineering Corp., Greenbelt, MD.), and Michael R. Pearlman (Smithsonian Astrophysical Observatory, Cambridge, MA.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 11 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

Recent improvements in the accuracy of modern satellite laser ranging (SLR) systems are strengthened by the new capability of many instruments to track an increasing number of geodetic satellite targets without significant scheduling conflict. This will allow the refinement of some geophysical parameters, such as solid Earth tidal effects and GM, and the improved temporal resolution of others, such as Earth orientation and station position. Better time resolution for the locations of fixed observatories will allow us to monitor more subtle motions at the stations, and transportable systems will be able to provide indicators of long term trends with shorter occupations. If we are to take advantage of these improvements, care must be taken to preserve the essential accuracy of an increasing volume of range observations at each stage of the data reduction process. SLR DATA SCREENING; LOCATION OF PEAK OF DATA DISTRIBUTION **c82**
Andrew T. Sinclair *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 10 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

At the 5th Laser Ranging Instrumentation Workshop held at Herstmonceux in 1984, consideration was given to the formation of on-site normal points by laser stations, and an algorithm was formulated. The algorithm included a recommendation that an iterated 3.0 x rms rejection criterion should be used to screen the data, and that arithmetic means should be formed within the normal point bins of the retained data. From Sept. 1990 onwards, this algorithm and screening criterion have been brought into effect by various laser stations for forming on-site normal points, and small variants of the algorithm are used by most analysis centers for forming normal points from full-rate data, although the data screening criterion they use ranges from about 2.5 to 3.0 x rms. At the CSTG Satellite Laser Ranging (SLR) Subcommission, a working group was set up in Mar. 1991 to review the recommended screening procedure. This paper has been influenced by the discussions of this working group, although the views expressed are primarily those of this author. The main thrust of this paper is that, particularly for single photon systems, a more important issue than data screening is the determination of the peak of a data distribution and hence, the determination of the bias of the peak from the mean. Several methods of determining the peak are discussed. Author (revised)

Avail: CASI HC A03/MF A06

As the CDSLR Network grows into the 1990's, it is undergoing many changes in both its capabilities and requirements. On the one hand, great progress has been made in terms of increasing the SLR systems' performance. Upgrades to the onsite computer and improved laser ranging hardware have greatly increased the number of satellite passes which can be acquired during an operating shift by reducing the amount of time

needed for operations other than actual ranging. On the other hand, more requirements have been placed on the systems. Many more satellites have become available, with more scheduled for launch, thus, increasing the likelihood of simultaneous satellite visibility. In addition, the possible scenarios required for ranging these many satellites are changing frequently, with conflicting priorities and needs. It became apparent that some tools needed to be developed to assist the planners in determining Network ranging priorities. Such tools have been developed at Bendix under the direction of NASA's Dynamics of the Solid Earth Project (DOSE) for both long range planning and routine operations to maximize the amount of data collected. This paper reviews some of these tools and describe their uses. Derived from text

Nd:YLF LASER FOR AIRBORNE/SPACEBORNE LASER RANGING c36

Joseph L. Dallas and Mark D. Selker *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 6 p (For primary document see N94-15552 03-19)

Avail: CASI HC A02/MF A06

In order to meet the need for light weight, long lifetime, efficient, short pulse lasers, a diode-pumped, Nd:YLF oscillator and regenerative amplifier is being developed. The anticipated output is 20 mJ per 10 picosecond pulse, running at a repetition rate of 40 Hz. The fundamental wavelength is at 1047 nm. The oscillator is pumped by a single laser diode bar and mode locked using an electro-optic, intra-cavity phase modulator. The output from the oscillator is injected as a seed into the regenerative amplifier. The regenerative amplifier laser crystal is optically pumped by two 60W quasi-cw laser diode bars. Each diode is collimated using a custom designed micro-lens bar. The injected 10 ps pulse from the oscillator is kept circulating within the regenerative amplifier until this nanojoule level seed pulse is amplified to 2-3 millijoules. At this point the pulse is ejected and sent on to a more standard single pass amplifier where the energy is boosted to 20 mJ. The footprint of the entire laser (oscillator-regenerative amplifier-amplifier) will fit on a 3 by 4 ft. optical pallet. Author (revised)

ALTERNATIVE WAVELENGTHS FOR LASER RANGING c36

Karel Hamal *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 2 p (For primary document see N94-15552 03-19)

Avail: CASI HC A01/MF A06

The following are considered to be necessary to accomplish multicolor laser ranging: the nature of the atmospheric dispersion and absorption, the satellite/lunar/ground retro-array characteristics, and ground/satellite ranging machine performance. The energy balance and jitter budget have to be considered as well. It is concluded that the existing satellite/laser retroreflectors seem inadequate for future experiments. The Raman Stokes/Anti-Stokes (0.68/0.43 micron) plus solid state detector appear to be promising instrumentation that satisfy the ground/satellite and satellite/ground ranging machine requirements on the precision, compactness, and data processing. NEW METHODS OF GENERATION OF ULTRASHORT LASER PULSES FOR RANGING c36

Helena Jelinkova, Karel Hamal, V. Kubecek, and Ivan Prochazka *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 6 p (For primary document see N94-15552 03-19)

Avail: CASI HC A02/MF A06

To reach the millimeter satellite laser ranging accuracy, the goal for nineties, new laser ranging techniques have to be applied. To increase the laser ranging precision, the application of the ultrashort laser pulses in connection with the new signal detection and processing techniques, is inevitable. The two wavelength laser ranging is one of the ways to measure the atmospheric dispersion to improve the existing atmospheric correction models and hence, to increase the overall system ranging accuracy to the desired value. We are presenting a review of several nonstandard techniques of ultrashort laser pulses generation, which may be utilized for laser ranging: compression of the nanosecond pulses using stimulated Brillouin and Raman backscattering; compression of the mode-locked pulses using Raman backscattering; passive mode-locking technique with nonlinear mirror; and passive mode-locking technique with the negative feedback. AN IMPROVED LIGHT SOURCE FOR LASER RANGING c36

Karel Hamal and Martin Richardson (University of Central Florida, Orlando.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 2 p (For primary document see N94-15552 03-19)

Avail: CASI HC A01/MF A06

The development of a new laser material, Cr-doped LiSAF, makes possible the development of a laser source for satellite ranging systems that is more superior in performance capabilities than current Nd:YAG-based laser sources. This new material offers the potential of shorter pulses and more preferable wavelengths (850 and 425 nm) than multiwavelength Nd:YAG systems, leading to superior ranging resolution and greater detection sensitivity. We are embarking on a feasibility study of a two-wavelength, mode-locked laser system based on Cr:LiSAF, providing shorter pulses for improved ranging resolution. Derived from text

PERFORMANCE OPTIMIZATION OF DETECTOR ELECTRONICS FOR MILLIMETER LASER RANGING c36

Sergio Cova, A. Lacaita, and Giancarlo Ripamonti (Milan Univ., Italy.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 18 p Sponsored in part by Italian Space Agency; CNR; and Italian Ministry of University and Research (For primary document see N94-15552 03-19)

Avail: CASI HC A03/MF A06

The front-end electronic circuitry plays a fundamental role in determining

the performance actually obtained from ultrafast and highly sensitive photodetectors. We deal here with electronic problems met working with microchannel plate photomultipliers (MCP-PMTs) and single photon avalanche diodes (SPADs) for detecting single optical photons and measuring their arrival time with picosecond resolution. The performance of available fast circuits is critically analyzed. Criteria for selecting the most suitable electronics are derived and solutions for exploiting the detector performance are presented and discussed. Author (revised)

TRACKING CAPABILITIES OF SPADS FOR LASER RANGING **c36**

F. Zappa, Giancarlo Ripamonti (Milan Univ., Italy.), A. Lacaita, Sergio Cova, and C. Samori *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 6 p Sponsored in part by Italian Space Agency; CNR; and Italian Ministry of University and Research (For primary document see N94-15552 03-19)

Avail: CASI HC A02/MF A06

The spatial sensitivity of Single-Photon Avalanche Diodes (SPADs) can be exploited in laser ranging measurements to finely tune the laser spot in the center of the detector sensitive area. We report the performance of a SPAD with 100 micron diameter. It features a time resolution better than 80 ps rms when operated 4V above V(b) at minus 30 C, and a spatial sensitivity better than 20 microns to radial displacements of the laser spot. New SPAD structures with auxiliary delay detectors are proposed. These improved devices could allow a two dimensional sensitivity, that could be employed for the design of pointing servos. Author (revised)

THE SOLID STATE DETECTOR TECHNOLOGY FOR PICOSECOND LASER RANGING **c76**

Ivan Prochazka *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 5 p (For primary document see N94-15552 03-19)

Avail: CASI HC A01/MF A06

We developed an all solid state laser ranging detector technology, which makes the goal of millimeter accuracy achievable. Our design and construction philosophy is to combine the techniques of single photon ranging, ultrashort laser pulses, and fast fixed threshold discrimination while avoiding any analog signal processing within the laser ranging chain. The all solid state laser ranging detector package consists of the START detector and the STOP solid state photon counting module. Both the detectors are working in an optically triggered avalanche switching regime. The optical signal is triggering an avalanche current buildup which results in the generation of a uniform, fast risetime output pulse. Derived from text

STREAK CAMERA BASED SLR RECEIVER FOR TWO COLOR ATMOSPHERIC MEASUREMENTS **c35**

Thomas K. Varghese, Christopher Clarke, Thomas Oldham, and Michael Selden *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 11 p (For primary document see N94-15552 03-19)

Avail: CASI HC A03/MF A06

To realize accurate two-color differential measurements, an image digitizing system with variable spatial resolution was designed, built, and integrated to a photon-counting picosecond streak camera, yielding a temporal scan resolution better than 300 femtosecond/pixel. The streak camera is configured to operate with 3 spatial channels; two of these support green (532 nm) and uv (355 nm) while the third accommodates reference pulses (764 nm) for real-time calibration. Critical parameters affecting differential timing accuracy such as pulse width and shape, number of received photons, streak camera/imaging system nonlinearities, dynamic range, and noise characteristics were investigated to optimize the system for accurate differential delay measurements. The streak camera output image consists of three image fields, each field is 1024 pixels along the time axis and 16 pixels across the spatial axis. Each of the image fields may be independently positioned across the spatial axis. Two of the image fields are used for the two wavelengths used in the experiment; the third window measures the temporal separation of a pair of diode laser pulses which verify the streak camera sweep speed for each data frame. The sum of the 16 pixel intensities across each of the 1024 temporal positions for the three data windows is used to extract the three waveforms. The waveform data is processed using an iterative three-point running average filter (10 to 30 iterations are used) to remove high-frequency structure. The pulse pair separations are determined using the half-max and centroid type analysis. Rigorous experimental verification has demonstrated that this simplified process provides the best measurement accuracy. To calibrate the receiver system sweep, two laser pulses with precisely known temporal separation are scanned along the full length of the sweep axis. The experimental measurements are then modeled using polynomial regression to obtain a best fit to the data. Data aggregation using normal point approach has provided accurate data fitting techniques and is found to be much more convenient than using the full rate single shot data. The systematic errors from this model have been found to be less than 3 ps for normal points. Author (revised)

The Laser Geodynamic Satellite-2 (LAGEOS-2) has undergone extensive optical testing at NASA Goddard Space Flight Center during 1989. The techniques included measuring the far field diffraction pattern using cw and pulsed lasers. In the pulsed measurement technique, response of the satellite was studied by measuring the far-field diffraction pattern (FFDP) as a function of pulsewidth, wavelength, polarization, position in the FFDP, detector/processing techniques, and satellite orientation. The purpose of the pulsed laser testing was two-fold: (1) to characterize the satellite optical response with the detector and signal processing electronics currently used in most SLR stations using the portable laser ranging standard, and (2) to characterize the satellite response for various conditions using the highest bandwidth optical detector (streak camera) available for the next generation of satellite laser ranging (SLR) technology. The portable ranging standard employed multiple measurement devices and an optical calibration scheme to eliminate range-dependent and amplitude-dependent systematics. These precautions were taken to eliminate/minimize instrumental errors and provide maximum accuracy. For LAGEOS orbit (6000 Km), ground stations are located 34 to 38 Mu radians off the axis of the return signal from the satellite; therefore, an optical mask was used to restrict the field of view (FOV) of detection to this annular region of the FFDP. The two measurement techniques were implemented using an aperture sharing scheme and complemented each other by providing mutual verification.

ANALYSIS OF TOPEX LASER RETROREFLECTOR ARRAY CHARACTERISTICS
Thomas K. Varghese *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 12 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

The joint U.S./French TOPEX/POSEIDON mission was successfully launched on August 10, 1992 for the study of ocean height variation using microwave altimetry. Accurate determination of the satellite orbit is paramount to the determination of the above phenomenon. To accomplish this, using laser ranging, the satellite is equipped with a laser retroreflector array (LRA) around the altimeter antennae. The goal of laser ranging is to obtain precision orbits with a radial accuracy of 13 cm to the center of mass of the satellite. This requires the laser range correction to the LRA reference be known at the sub-cm level and is quite a challenge considering the geometry of the LRA. Detailed studies were initiated by the TOPEX project office (Christensen) under the auspices of the CDP/DOSE project (Degnan) at Goddard Space Flight Center. Author (revised)

HISTORICAL MOBLAS SYSTEM CHARACTERIZATION **c36**
Van S. Husson *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 23 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

This paper is written as a direct response to the published NASA Laser Geodynamic Satellite (LAGEOS) orbital solution SL7.1, in order to close the data information loop with an emphasis on the NASA Mobile Laser Ranging System's (MOBLAS) LAGEOS full rate data since November 1, 1983. A preliminary analysis of the supporting information (i.e. satellite laser ranging system eccentricities and system dependent range and time bias corrections) contained in SL7.1 indicated centimeter (cm) level discrepancies. In addition, a preliminary analysis of the computed monthly MOBLAS range biases from SL7.1 appear to show cm level systematic trends, some of which appear to be 'real', particularly in the 1984 to 1987 time period. This paper is intended to be a reference document for known MOBLAS systematic errors (magnitude and direction) and for supporting MOBLAS information (eccentricities, hardware configurations, and potential data problem periods). Therefore, this report is different than your typical system characterization report, but will be more valuable to the user. The MOBLAS error models and supporting information contained in this paper will be easily accessible from the Crustal Dynamics Data Information System (CDDIS). Author (revised)

OPTIMUM WAVELENGTHS FOR TWO COLOR RANGING **c32**
John J. Degnan *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 14 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

The range uncertainties associated with the refractive atmosphere can be mitigated by the technique of two color, or dual wavelength, ranging. The precision of the differential time of flight (DTOF) measurement depends on the atmospheric dispersion between the two wavelengths, the received pulsewidths and photoelectron counts, and on the amount of temporal averaging. In general, the transmitted wavelengths are not independently chosen but instead are generated via nonlinear optics techniques (harmonic crystals, Raman scattering, etc.) which also determine their relative pulsewidths. The mean received photoelectrons at each wavelength are calculated via the familiar radar link equation which contains several wavelength dependent parameters. By collecting the various wavelength dependent terms, one can define a wavelength figure of merit for a two color laser ranging system. In this paper, we apply the wavelength figure of merit to the case of an extremely clear atmosphere and draw several conclusions regarding the relative merits of fundamental-second harmonic, fundamental-third harmonic, second-third harmonic, and Raman two color systems. We find that, in spite of the larger dispersion between wavelengths, fundamental-third harmonic systems have the lowest figure of merit due to a combination of poor detector performance at the fundamental and poor atmospheric transmission at the third harmonic. The fundamental-second harmonic systems (approximately 700 nm and 350 nm) have the highest figure of merit, but second-third harmonic systems, using fundamental transmitters near 1000 nm, are a close second. Raman-shifted transmitters appear to offer no advantage over harmonic systems because of the relatively small wavelength separation that can be achieved in light gases such as hydrogen and the lack of good ultrashort pulse transmitters with an optimum fundamental wavelength near 400 nm. TWO COLOR SATELLITE LASER RANGING UPGRADES AT GODDARD'S 1.2m TELESCOPE FACILITY **c35**
Thomas W. Zagwodzki, Jan F. McGarry, John J. Degnan, and Thomas K. Varghese (Bendix Field Engineering Corp., Seabrook, MD.) *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 13 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

The ranging laboratory at Goddard's 1.2 m telescope tracking facility has recently been upgraded to include a single photoelectron sensitive Hamamatsu streak camera-based range receiver which uses doubled and tripled Nd:YAG frequencies for satellite laser ranging. Other ranging system upgrades include a new continuum laser, which will deliver up to 30 millijoules (mJ) at both 532 and 355 nm at a pulsewidth of 30 picoseconds (FWHM),

and replacement of both ranging and tracking computers with COMPAQ 386 based systems. Preliminary results using a photomultiplier-tube based receiver and waveform digitizer indicate agreement within the accuracy of the measurement with the theoretical Marini and Murray model for atmospheric refraction. Two color streak camera measurements are used to further analyze the accuracy of these and other atmospheric refraction models. Author (revised)

Avail: CASI HC A02/MF A06

The WLRS (Wettzell Laser Ranging System) allows the simultaneous tracking of satellites on two different wavelengths. These are the fundamental frequency of Nd:YAG at 1.064 microns and the second harmonic at 532 nm. Range measurements to the satellite LAGEOS were carried out with different experimental set-ups, after developing a detector unit based on a silicon avalanche photodiode in Geiger mode, which is sufficiently sensitive in the infrared domain. An approach towards a quantitative interpretation of the data is suggested and discussed briefly. Author (revised)

Avail: CASI HC A03/MF A06

The principal technical challenge in designing a millimeter accuracy satellite to support two color observations at high altitudes is to provide high optical cross-section simultaneously with minimal pulse spreading. In order to address this issue, we provide, a brief review of some fundamental properties of optical retroreflectors when used in spacecraft target arrays, develop a simple model for a spherical geodetic satellite, and use the model to determine some basic design criteria for a new generation of geodetic satellites capable of supporting millimeter accuracy two color laser ranging. We find that increasing the satellite diameter provides: a larger surface area for additional cube mounting thereby leading to higher cross-sections; and makes the satellite surface a better match for the incoming planar phasefront of the laser beam. Restricting the retroreflector field of view (e.g. by recessing it in its holder) limits the target response to the fraction of the satellite surface which best matches the optical phasefront thereby controlling the amount of pulse spreading. In surveying the arrays carried by existing satellites, we find that European STARLETTE and ERS-1 satellites appear to be the best candidates for supporting near term two color experiments in space. When ranging to satellites with lasers, there are several principal contributions to the error budget: from the laser ranging system on the ground, from the satellite retroarray geometry, and from the atmosphere. Using a single wavelength, we have routinely achieved a ranging precision of 8 millimeters when ranging to the ERS-1 and Starlette satellites. The systematic error of the atmosphere, assuming the existing dispersion models, is expected to be of the order of 1 cm. Multiple wavelengths ranging might contribute to the refinement of the existing models. Taking into account the energy balance, the existing picosecond lasers and the existing receiver and detection technology, several pairs or multiple wavelengths may be considered. To be able to improve the atmospheric models to the subcentimeter accuracy level, the differential time interval (DTI) has to be determined within a few picoseconds depending on the selected wavelength pair. There exist several projects based on picosecond lasers as transmitters and on two types of detection techniques: one is based on photodetectors, like photomultipliers or photodiodes connected to the time interval meters. Another technique is based on the use of a streak camera as an echo signal detector, temporal analyzer, and time interval vernier. The temporal analysis at a single wavelength using the streak camera showed the complexity of the problem. Derived from text

NEW PERSPECTIVES FOR HIGH ACCURACY SLR WITH SECOND GENERATION GEODESIC SATELLITES

Glenn Lund *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 9 p (For primary document see N94-15552 03-19)

Avail: CASI HC A02/MF A06

This paper reports on the accuracy limitations imposed by geodesic satellite signatures, and on the potential for achieving millimetric performances by means of alternative satellite concepts and an optimized 2-color system tradeoff. Long distance laser ranging, when performed between a ground (emitter/receiver) station and a distant geodesic satellite, is now reputed to enable short arc trajectory determinations to be achieved with an accuracy of 1 to 2 centimeters. This state-of-the-art accuracy is limited principally by the uncertainties inherent to single-color atmospheric path length correction. Motivated by the study of phenomena such as postglacial rebound, and the detailed analysis of small-scale volcanic and strain deformations, the drive towards millimetric accuracies will inevitably be felt. With the advent of short pulse (less than 50 ps) dual wavelength ranging, combined with adequate detection equipment (such as a fast-scanning streak camera or ultra-fast solid-state detectors) the atmospheric uncertainty could potentially be reduced to the level of a few millimeters, thus, exposing other less significant error contributions, of which by far the most significant will then be the morphology of the retroreflector satellites themselves. Existing geodesic satellites are simply dense spheres, several 10's of cm in diameter, encrusted with a large number (426 in the case of LAGEOS) of small cube-corner reflectors. A single incident pulse, thus, results in a significant number of randomly phased, quasi-simultaneous return pulses. These combine coherently at the receiver to produce a convolved interference waveform which cannot, on a shot to shot basis, be accurately and unambiguously correlated to the satellite center of mass. This paper proposes alternative geodesic satellite concepts, based on the use of a very small number of cube-corner retroreflectors, in which the above difficulties are eliminated while ensuring, for a given emitted pulse, the return of a single clean pulse with an adequate cross-section.

STATE-OF-THE-ART SATELLITE LASER RANGE MODELING FOR GEODETIC AND OCEANOGRAPHIC APPLICATIONS **c36**

Steve M. Klosko (Hughes STX, Inc., Lanham, MD.) and David E. Smith *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 14 p (For primary document see N94-15552 03-19)

Avail: CASI HC A03/MF A06

Significant improvements have been made in the modeling and accuracy of Satellite Laser Range (SLR) data since the launch of LAGEOS in 1976. Some of these include: improved models of the static geopotential, solid-Earth and ocean tides, more advanced atmospheric drag models, and the adoption of the J2000 reference system with improved nutation and precession. Site positioning using SLR systems currently yield approximately 2 cm static and 5 mm/y kinematic descriptions of the geocentric location of these sites. Incorporation of a large set of observations from advanced Satellite Laser Ranging (SLR) tracking systems have directly made major contributions to the gravitational fields and in advancing the state-of-the-art in precision orbit determination. SLR is the baseline tracking system for the altimeter bearing TOPEX/Poseidon and ERS-1 satellites and thus, will play an important role in providing the Conventional Terrestrial Reference Frame for instantaneously locating the geocentric position of the ocean surface over time, in providing an unchanging range standard

for altimeter range calibration, and for improving the geoid models to separate gravitational from ocean circulation signals seen in the sea surface. Nevertheless, despite the unprecedented improvements in the accuracy of the models used to support orbit reduction of laser observations, there still remain systematic unmodeled effects which limit the full exploitation of modern SLR data. IMPROVEMENT OF SLR ACCURACY, A POSSIBLE NEW STEP
Michel Kasser *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 7 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

The satellite laser ranging (SLR) technology experienced a large number of technical improvements since the early 1970's, leading now to a millimetric instrumental accuracy. Presently, it appears as useless to increase these instrumental performances as long as the atmospheric propagation delay suffers its actual imprecision. It has been proposed for many years to work in multiwavelength mode, but up to now the considerable technological difficulties of subpicosecond timing have seriously delayed such an approach. Then a new possibility is proposed, using a device which is not optimized now for SLR but has already given good results in the lower troposphere for wind measurement: the association of a radar and a sodar. While waiting for the 2-lambda methodology, this one could provide an atmospheric propagation delay at the millimeter level during a few years with only little technological investment. Avail: CASI HC A02/MF A06

Since the launch of ERS-1, the D-PAF (German Processing and Archiving Facility) provides regularly orbit predictions for the worldwide SLR (Satellite Laser Ranging) tracking network. The weekly distributed orbital elements are so called tuned IRV's and tuned SAO-elements. The tuning procedure, designed to improve the accuracy of the recovery of the orbit at the stations, is discussed based on numerical results. This shows that tuning of elements is essential for ERS-1 with the currently applied tracking procedures. The orbital elements are updated by daily distributed time bias functions. The generation of the time bias function is explained. Problems and numerical results are presented. The time bias function increases the prediction accuracy considerably. Finally, the quality assessment of ERS-1 orbit predictions is described. The accuracy is compiled for about 250 days since launch. The average accuracy lies in the range of 50-100 ms and has considerably improved. Derived from text

Avail: CASI HC A02/MF A06

The importance of an accurate knowledge of the time bias corrections to predicted orbits to a satellite laser ranging (SLR) observer, especially for low satellites, is highlighted. Sources of time bias values and the optimum strategy for extrapolation are discussed from the viewpoint of the observer wishing to maximize the chances of getting returns from the next pass. What is said may be seen as a commercial encouraging wider and speedier use of existing data centers for mutually beneficial exchange of time bias data. Author (revised)

We describe our methods of fitting a smoothing function to observational range differences from a predicted orbit, by deducing corrections to the orbit in the radial and along-track directions. The method has been used on observations of a variety of satellites, and using predicted orbits computed both by numerical integration using IRV's as starting values and analytically from orbital elements. The along-track corrections to the predicted orbit have been successfully used in the form of time biases to improve subsequent predictions, and a statistical test has been devised to ensure that the range residuals may be used to form unbiased quick look normal points. There are several existing communication methods to deliver data from the satellite laser ranging (SLR) station to the SLR data center and back: telephonmodem, telex, and computer networks. The SLR scientific community has been exploiting mainly INTERNET, BITNET/EARN, and SPAN. The total of 56 countries are connected to INTERNET and the number of nodes is exponentially growing. The computer networks mentioned above and others are connected through E-mail protocol. The scientific progress of SLR requires the increase of communication speed and the amount of the transmitted data. The TOPEX/POSEIDON test campaign

required to deliver Quick Look data (1.7 kB/pass) from a SLR site to SLR data center within 8 hours and full rate data (up to 500 kB/pass) within 24 hours. We developed networking for the remote SLR station in Helwan, Egypt. The reliable scheme for data delivery consists of: compression of MERIT2 format (up to 89 percent), encoding to ASCII Me (files); and e-mail sending from SLR station--e-mail receiving, decoding, and decompression at the center. We do propose to use the ZIP method for compression/decompression and the UUCODE method for ASCII encoding/decoding. This method will be useful for stations connected via telephonemodems or commercial networks. The electronics delivery could solve the problem of the too late receiving of the FR data by SLR data center. Author (revised)

Avail: CASI HC A02/MF A06

Laser ranging systems now managed by the NASA Dynamics of the Solid Earth (DOSE) and operated by the Bendix Field Engineering Corporation, the University of Hawaii, and the University of Texas have produced a wealth on interdisciplinary scientific data over the last three decades. Despite upgrades to the most of the ranging station subsystems, the control computers remain a mix of 1970's vintage minicomputers. These encompass a wide range of vendors, operating systems, and languages, making hardware and software support increasingly difficult. Current technology allows replacement of controller computers at a relatively low cost while maintaining excellent processing power and a friendly operating environment. The new controller systems are now being designed using IBM-PC-compatible 80486-based microcomputers, a real-time Unix operating system (LynxOS), and X-windows/Motif IB, and serial interfaces have been chosen. This design supports minimizing short and long term costs by relying on proven standards for both hardware and software components. Currently, the project is in the design and prototyping stage with the first systems targeted for production in mid-1993. Author (revised)

Avail: CASI HC A02/MF A06

New computer technology and resources must be successfully integrated into CDSLR station operations to manage new complex operational tracking requirements, support the on site production of new data products, support ongoing station performance improvements, and to support new station communication requirements. The NASA CDSLR Network is in the process of upgrading station computer resources with HP UNIX workstations, designed to automate a wide range of operational station requirements. The primary HP upgrade objective was to relocate computer intensive data system tasks from the controller computer to a new advanced computer environment designed to meet the new data system requirements. The HP UNIX environment supports fully automated real time data communications, data management, data processing, and data quality control. Automated data compression procedures are used to improve the efficiency of station data communications. In addition, the UNIX environment supports a number of semi-automated technical and administrative operational station tasks. The x window user interface generates multiple simultaneous color graphics displays, providing direct operator visibility and control over a wide range of operational station functions. A COMPUTER-CONTROLLED x-y OFFSET GUIDING STAGE FOR THE MLRS **c35**

Peter J. Shelus, A. L. Whipple, J. R. Wiant, Randall L. Ricklefs, and Frank M. Melsheimer (DFM Engineering, Inc., Longmont, CA.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 5 p (For primary document see N94-15552 03-19)

Avail: CASI HC A01/MF A06

The MLRS has experienced excellent success in its lunar and artificial satellite laser ranging operations during its many years of operation, in spite of its relatively small 'receive' aperture. We continue to strive, however, for a greater volume of data, together with better accuracy and precision. We have just now completed the design, construction, and implementation of a computer controlled x-y offset guiding stage for the MLRS, analogous to the manual one that had been a part of the original 2.7-m lunar laser ranging system on Mt. Locke at McDonald Observatory. In the past, we had been hampered by the lack of a satisfactory hardware design which could fit within the very cramped quarters of the MLRS telescope's tail piece. Recently, with funding support from the U.S. Naval Observatory and the design and construction expertise of DFM Engineering, Inc., a satisfactory instrument has been specified, designed, built, and installed. This instrument will greatly expand MLRS observational opportunities by allowing the observing crews to actively guide on visible off axis lunar surface features or background stars while the on-axis lunar surface retroreflector targets are in the dark. This paper describes this instrument and its present implementation at the MLRS. Author (revised)

LUNAR LASER RANGING DATA PROCESSING IN A UNIX/X WINDOWS ENVIRONMENT **c36**

Randall L. Ricklefs and Judit G. Ries *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 8 p (For primary document see N94-15552 03-19)

Avail: CASI HC A02/MF A06

In cooperation with the NASA Crustal Dynamics Project initiative placing workstation computers at each of its laser ranging stations to handle data filtering and normalpointing, MLRS personnel have developed a new generation of software to provide the same services for the lunar laser ranging data type. The Unix operating system and X windows/Motif provides an environment for both batch and interactive filtering and normalpointing as well as prediction calculations. The goal is to provide a transportable and maintainable data reduction environment. This software and some sample displays are presented. that the lunar (or satellite) datacould be processed on one computer while data was taken on the other. The reduction of the data was totally interactive and in no way automated. In addition, lunar predictions were produced on-site, another first in the effort to down-size historically mainframe-based applications. Extraction of earth rotation parameters was at one time attempted on site in near-realtime. In 1988, the Crustal Dynamics Project SLR Computer Panel mandated the installation of Hewlett-Packard 9000/360 Unix workstations at each NASA-operated laser ranging station to relieve the aging controller computers of much of their data and communications handling responsibility and to provide on-site data filtering and normal pointing for a growing list of artificial satellite targets. This was seen by MLRS staff as an opportunity to provide a better lunar data processing environment as well.

MATERA LASER RANGING OBSERVATORY (MLRO): AN OVERVIEW **c14**
Thomas K. Varghese, Winfield M. Decker, Henry A. Crooks, and Giuseppe Bianco (Italian Space Agency, Matera.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 5 p (For primary document see N94-15552 03-19)
Avail: CASI HC A01/MF A06

The Agenzia Spaziale Italiana (ASI) is currently under negotiation with the Bendix Field Engineering Corporation (BFEC) of the Allied Signal Aerospace Company (ASAC) to build a state-of-the-art laser ranging observatory for the Centro di Geodesia Spaziale, in Matera, Italy. The contract calls for the delivery of a system based on a 1.5 meter afocal Cassegrain astronomical quality telescope with multiple ports to support a variety of experiments for the future, with primary emphasis on laser ranging. Three focal planes, viz. Cassegrain, Coude, and Nasmyth will be available for these experiments. The open telescope system will be protected from dust and turbulence using a specialized dome which will be part of the building facilities to be provided by ASI. The fixed observatory facility will be partitioned into four areas for locating the following: laser, transmit/receive optics, telescope/dome enclosure, and the operations console. The optical tables and mount rest on a common concrete pad for added mechanical stability. Provisions will be in place for minimizing the effects of EMI, for obtaining maximum cleanliness for high power laser and transmit optics, and for providing an ergonomic environment fitting to a state-of-the-art multipurpose laboratory. The system is currently designed to be highly modular and adaptable for scaling or changes in technology. It is conceived to be a highly automated system with superior performance specifications to any currently operational system. Provisions are also made to adapt and accommodate changes that are of significance during the course of design and integration.

In this article, we describe a new satellite laser ranging capability which is a joint effort between the Naval Research Laboratory and Air Force Optical Tracking Facility at Malabar, Florida. Initial measurements off LAGEOS indicate that uncorrected radial range rms values of 8 mm are readily achievable. The number of photoelectron counts are on the order of 180 which are off by an order of magnitude from predicted values.

A satellite laser ranging system with an accuracy of the level of centimeter has been successfully developed at the Institute of Seismology, State Seismological Bureau with the cooperation of the Institute of Geodesy and Geophysics, Chinese Academy of Science. With significant improvements on the base of the second generation SLR system developed in 1985, ranging accuracy of the new system has been upgraded from 15 cm to 3-4 cm. Measuring range has also been expanded, so that the ETALON satellite with an orbit height of 20,000 km launched by the former U.S.S.R. can now be tracked. Compared with the 2nd generation SLR system, the newly developed system has the following improvements. A Q modulated laser is replaced by a mode-locked YAG laser. The new device has a pulse width of 150 ps and a repetition rate of 1-4 pps. A quick response photomultiplier has been adopted as the receiver for echo; for example, the adoption of the MCP tube has obviously reduced the jitter error of the transit time and has improved the ranging accuracy. The whole system is controlled by an IBM PC/XT Computer to guide automatic tracking and measurement. It can carry out these functions for satellite orbit calculation, real-time tracking and adjusting, data acquisition and the preprocessed of observing data, etc. The automatization level and reliability of the observation have obviously improved. This presentation describes the upgrades to the Transportable Laser Ranging Systems serial number three (TLRS-3), and the impact that these upgrades will have on the TLRS-3 performance in the field. The four major areas of system upgrades are the HP-380 computer, the Optical Attenuation Mechanism (OAM), the upgraded spatial, spectral and temporal filtering for improved daylight ranging capability, and the software upgrade to enable the system to track the Etalon satellites. The TLRS-3 was returned to the Goddard Geophysical and Astronomical Observatory (GGAO) in December 1991 for system upgrades in preparation of the TOPEX/POSEIDON campaign scheduled to begin in the summer of 1992. Many system upgrades were incorporated into the system while interleaving planned facility maintenance making TLRS-3 a more versatile and more dependable laser ranging system. The TLRS-3 was initially baselined with the MOBLAS-7 via simultaneous satellite ranging on the LAGEOS, Ajisai, Starlette, and ERS-I satellites. During the upgrades and following completion of the system upgrades intercomparisons with the MOBLAS-7 were made to verify the integrity and accuracy of the system changes. Several other groups of personnel participated in the TLRS-3 upgrade and they are: the Survey Section, the Precision Measurement Equipment Laboratory, the Architectural and Engineering Services Department, the Precision Timing Section, and the station personnel at TLRS-3 and MOBLAS-7.

The Modular Transportable Laser Ranging Systems (MTLRS-1 and MTLRS-2) have been designed in the early eighties and have been in operation very successfully since 1984. The original design of the electronic control system was based on the philosophy of parallel processing, but these ideas could at that time only be implemented to a very limited extent. This present system utilizes two MOTOROLA 6800 8-bit processors slaved to a HP A-600 micro-computer. These processors support the telescope tracking system and the data-acquisition/formatting, respectively. Nevertheless, the overall design still is largely hardware oriented. Because the system is now some nine years old, aging of components increases the risk of malfunctioning and some components or units are outdated and not available anymore. The control system for MTLRS is now being re-designed completely, based on the original philosophy of parallel processing, making use of contemporary advanced electronics and processor technology. The new design aims at the requirements for Satellite Laser Ranging (SLR) in the nineties, making use of the extensive operational experience obtained with the two transportable systems.

Horizontal variations in the atmospheric refractivity are a limiting error source for many precise laser and radio space geodetic techniques. This experiment was designed to directly measure horizontal variations in atmospheric refractivity, for the first time, by using 2 color laser ranging measurements to an aircraft. The 2 color laser system at the Goddard

Optical Research Facility (GORF) ranged to a cooperative laser target package on a T-39 aircraft. Circular patterns which extended from the southern edge of the Washington D.C. Beltway to the southern edge of Baltimore, MD were flown counter clockwise around Greenbelt, MD. Successful acquisition, tracking, and ranging for 21 circular paths were achieved on three flights in August 1992, resulting in over 20,000 two color ranging measurements. Author (revised)

GLRS-R 2-COLOUR RETROREFLECTOR TARGET DESIGN AND PREDICTED PERFORMANCE **c36**
Glenn Lund *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 16 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

This paper reports on the retroreflector ground-target design for the GLRS-R spaceborne dual-wavelength laser ranging system. The described passive design flows down from the requirements of high station autonomy, high global FOV (up to 60 degrees zenith angle), little or no multiple pulse returns, and adequate optical cross section for most ranging geometries. The proposed solution makes use of 5 hollow cube-corner retroreflectors of which one points to the zenith and the remaining four are inclined from the vertical at uniform azimuthal spacings. The need for fairly large (is approximately 10 cm) retroreflectors is expected (within turbulence limitations) to generate quite narrow diffraction lobes, thus placing non-trivial requirements on the vectorial accuracy of velocity aberration corrections. A good compromise solution is found by appropriately spoiling just one of the retroreflector dihedral angles from 90 degrees, thus generating two symmetrically oriented diffraction lobes in the return beam. The required spoil angles are found to have little dependence on ground target latitude. Various link budget analyses are presented, showing the influence of such factors as point-ahead optimization, turbulence, ranging angle, atmospheric visibility and ground target thermal deformations. The Geodynamic Laser Ranging System (GLRS) is one of several instruments being developed by the National Aeronautics and Space Administration (NASA) for implementation as part of the Earth Observing System in the mid-1990s (Cohen et al., 1987; Bruno et al., 1988). It consists of a laser transmitter and receiver in space and an array of retroreflectors on the ground. The transmitter produces short (100 ps) pulses of light at two harmonics (0.532 and 0.355 microns) of the Nd:YAG laser. These propagate to a retroreflector on the ground and return. The receiver collects the reflected light and measures the round-trip transit time. Ranging from several angles accurately determines the position of the retroreflector, and changes in position caused by geophysical processes can be monitored. Derived from text

DEVELOPMENT OF THE MARS OBSERVER LASER ALTIMETER (MOLA) **c36**
Bertrand L. Johnson, Jr et al *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 3 p (For primary document see N94-15552 03-19)
Avail: CASI HC A01/MF A06

The Mars Observer (MO) spacecraft payload scientific mission is to gather data on Martian global topography, gravity, weather, magnetic field and its interaction with the solar flux, surface chemistry, and mineralogy over one Mars year. In mid-1988 the need for a replacement altimeter as part of the payload complement arose. The Mars Observer Laser Altimeter (MOLA) was proposed by GSFC as an in-house effort and shortly afterward was 'conditionally' accepted. Constraints on funding, schedule, power, and mass were imposed with periodic reviews during the instrument development to authorize continuation. MOLA was designed, tested, and delivered in less than 36 months and integrated with the spacecraft. During spacecraft payload testing, the laser failed due to contamination in the laser cavity. In only 6 months, the laser was removed, rebuilt from spare parts, retested, and the instrument reassembled, realigned, requalified, and again delivered for spacecraft integration. Other aspects of the development of the MOLA are presented. Derived from text

BENCH CHECKOUT EQUIPMENT FOR SPACEBORNE LASER ALTIMETER SYSTEMS **c35**
James C. Smith, Gregory C. Elman (Ressler Associates, Inc., Laurel, MD.), Kent D. Christian (Bendix Field Engineering Corp., Columbia, MD.), John F. Cavanaugh, Luis Ramos-Izquierdo, and Dan E. Hopf (Science Systems and Applications, Inc., Lanham, MD.) *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 22 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

This paper addresses the requirements for testing and characterizing spaceborne laser altimeter systems. The Bench Checkout Equipment (BCE) system, test requirements, and flow-down traceability from the instrument system's functional requirements will also be presented. Mars Observer Laser Altimeter (MOLA) and the MOLA BCE are presented as representative of a 'typical' laser altimeter and its corresponding test system. The testing requirements of other or future laser altimeter systems may vary slightly due to the specific spacecraft interface and project requirements. MOLA, the first solid-state interplanetary laser altimeter, was designed to be operational in Mars orbit for two Earth years. MOLA transmits a 7.5 ns pulse at a wavelength of 1.064 microns with a 0.25 mr beam divergence and a pulse repetition rate of 10 Hz. The output energy is specified at 45 mj at the beginning of mapping orbit and 30 mj at the end of one Martian year. MOLA will measure the laser pulse transit time from the spacecraft to the Mars surface and return to a resolution of 1.5 meters. Derived from text

MARS LASER ALTIMETER BASED ON A SINGLE PHOTON RANGING TECHNIQUE **c36**
Ivan Prochazka, Karel Hamal, B. Sopko, and S. Pershin (Academy of Sciences, USSR, Moscow.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 4 p (For primary document see N94-15552 03-19)
Avail: CASI HC A01/MF A06

The Mars 94/96 Mission will carry, among others things, the balloon probe experiment. The balloon with the scientific cargo in the gondola underneath will drift in the Mars atmosphere, its altitude will range from zero, in the night, up to 5 km at noon. The accurate gondola altitude will be determined by an altimeter. As the Balloon gondola mass is strictly limited, the altimeter total mass and power consumption are critical; maximum allowed is a few hundred grams a few tens of mWatts of average power consumption. We did propose, design, and construct the laser altimeter based on the single photon ranging technique. Topics covered include the following: principle of operation, altimeter construction, and ground tests. Derived from text

MULTI-BEAM LASER ALTIMETER **c36**
Jack L. Bufton, David J. Harding, and Luis Ramos-Izquierdo *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 9 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

Laser altimetry provides a high-resolution, high-accuracy method for measurement of the elevation and horizontal variability of Earth-surface topography. The basis of the measurement is the timing of the round-trip propagation of short-duration pulses of laser radiation between a spacecraft and the Earth's surface. Vertical resolution of the altimetry measurement is determined primarily by laser pulsewidth, surface-induced spreading in time of the reflected pulse, and the timing precision of the altimeter electronics. With conventional gain-switched pulses from solid-state lasers and sub-nsec resolution electronics, sub-meter vertical range resolution is possible from

orbital attitudes of several hundred kilometers. Horizontal resolution is a function of laser beam footprint size at the surface and the spacing between successive laser pulses. Laser divergence angle and altimeter platform height above the surface determine the laser footprint size at the surface, while laser pulse repetition-rate, laser transmitter beam configuration, and altimeter platform velocity determine the space between successive laser pulses. Multiple laser transitters in a singlaltimeter instrument provide across-track and along-track coverage that can be used to construct a range image of the Earth's surface. Other aspects of the multi-beam laser altimeter are discussed. Derived from text

SATELLITE LASER STATION HELWAN STATUS 1992 Abstract Only **c14**

M. Cech, Karel Hamal, Helena Jelinkova, Antonin Novotny, Ivan Prochazka, B. B. Baghos (National Research Inst. of Astronomy and Geophysics, Helwan, Egypt.), Y. Helali (National Research Inst. of Astronomy and Geophysics, Helwan, Egypt.), and M. J. Tawadros (National Research Inst. of Astronomy and Geophysics, Helwan, Egypt.) *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 1 p Sponsored in part by Smithsonian Astrophysical Observatory (For primary document see N94-15552 03-19)
(Contracts ERS-1/7831/91; ERS-1/7831/92)
Avail: CASI HC A01/MF A06

The Satellite Laser Station Helwan has been operated jointly by the National Research Institute of Astronomy and Geophysics in Helwan, Egypt and the Czech Technical University in Prague, Czechslovakia. The station components have been carefully tuned to increase the systems overall stability and reliability critical for the remote location. The mount correction model based on the Gaussian smoothing has been implemented to simplify the blind satellite acquisition and tracking. The on-site normal points generation algorithm has been implemented, the station has been connected to the international information network. The ERS-1 satellite has been included into the tracking schedule. The station range capability has been verified by experimental Etalon 1 ranging by April 1992. The ranging precision of 2-3 centimeters is obtained when ranging to ERS-1, Starlette, and Lageos satellites. Derived from text

OPTICAL ATTENUATION MECHANISM UPGRADES, MOBLAS, AND TLRS SYSTEMS

Richard Eichinger, Toni Johnson, Paul Malitson, Thomas Oldham, and Loyal Stewart *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 12 p (For primary document see N94-15552 03-19)
Avail: CASI HC A03/MF A06

This poster presentation describes the Optical Attenuation Mechanism (OAM) Upgrades to the MOBLAS and TLRS Crustal Dynamics Satellite Laser Ranging (CDSLR) systems. The upgrades were for the purposes of preparing these systems to laser range to the TOPEX/POSEIDON spacecraft when it will be launched in the summer of 1992. The OAM permits the laser receiver to operate over the expected large signal dynamic range from TOPEX/POSEIDON and it reduces the number of pre- and post-calibrations for each satellite during multi-satellite tracking operations. It further simplifies the calibration bias corrections that had been made due to the pass-to-pass variation of the photomultiplier supply voltage and the transmit filter glass thickness. The upgrade incorporated improvements to the optical alignment capability of each CDSLR system through the addition of a CCD camera into the MOBLAS receive telescope and an alignment telescope onto the TLRS optical table. The OAM is stepper motor and microprocessor based; and the system can be controlled either manually by a control switch panel or computer controlled via an EIA RS-232C serial interface. The OAM has a neutral density (ND) range of 0.0 to 4.0 and the positioning is absolute referenced in steps of 0.1 ND. Both the fixed transmit filter and the daylight filter are solenoid actuated with digital inputs and outputs to and from the OAM microprocessor. During automated operation, the operator has the option to overide the remote control and control the OAM system via a local control switch panel.

PERFORMANCE COMPARISON OF HIGH SPEED MICROCHANNEL PLATE PHOTOMULTIPLIER TUBES **c33**

Thomas Varghese, Michael Selden, and Thomas Oldham *In* NASA. Goddard Space Flight Center, Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 9 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

The transit time spread characteristics of high speed microchannel photomultipliers has improved since the upgrade of the NASA CDSLR network to MCP-PMT's in the mid-1980's. The improvement comes from the incorporation of 6 micron (pore size) microchannels and offers significant improvement to the satellite ranging precision. To examine the impact on ranging precision, two microchannel plate photomultiplier tubes (MCP-PMT) were evaluated for output pulse characteristics and temporal jitter. These were a Hamamatsu R 2566 U-7 MCP-PMT (6 micron) and an ITT 4129f MCP-PMT (12 micron). Derived from text

STATION REPORT ON THE GODDARD SPACE FLIGHT CENTER (GSFC) 1.2 METER TELESCOPE FACILITY **c89**

Jan F. McGarry, Thomas W. Zagwodzki, Arnold Abbott, John J. Degnan, Jack W. Cheek (Hughes STX, Inc., Lanham, MD.), Richard S. Chabot (Bendix Field Engineering Corp., Seabrook, MD.), David A. Grolemund (Bendix Field Engineering Corp., Seabrook, MD.), and Jim D. Fitzgerald (Bendix Field Engineering Corp., Seabrook, MD.) *In its* Eighth International Workshop on Laser Ranging Instrumentation Jun. 1993 8 p (For primary document see N94-15552 03-19)
Avail: CASI HC A02/MF A06

The 1.2 meter telescope system was built for the Goddard Space Flight Center (GSFC) in 1973-74 by the Kollmorgen Corporation as a highly accurate tracking telescope. The telescope is an azimuth-elevation mounted six mirror Coude system. The facility has been used for a wide range of experimentation including helioseismology, two color refractometry, lunar laser ranging, satellite laser ranging, visual tracking of rocket launches, and most recently satellite and aircraft streak camera work. The telescope is a multi-user facility housed in a two story dome with the telescope located on the second floor above the experimenter's area. Up to six experiments can be accommodated at a given time, with actual use of the telescope being determined by the location of the final Coude mirror. The telescope facility is currently one of the primary test sites for the Crustal Dynamics Network's new UNIX based telescope controller software, and is also the site of the joint Crustal Dynamics Project / Photonics Branch two color research into atmospheric refraction. MICROWAVE REFLECTOMETER IONIZATION SENSOR

Joseph Seals, Jeffrey A. Fordham, Robert G. Pauley (Georgia Tech Research Inst., Atlanta.), and Mario D. Simonutti (Millitech Corp., South Deerfield, MA.) Oct. 1993 402 p
(Contract NAS1-19063; RTOP 505-64-12-04)
(NASA-CR-191464; NAS 1.26:191464) Avail: CASI HC A18/MF A04

The development of the Microwave Reflectometer Ionization Sensor (MRIS) Instrument for use on the Aeroassist Flight Experiment (AFE) spacecraft is described. The instrument contract was terminated, due to cancellation of the AFE program, subsequent to testing of an engineering

development model. The MRIS, a four-frequency reflectometer, was designed for the detection and location of critical electron density levels in spacecraft reentry plasmas. The instrument would sample the relative magnitude and phase of reflected signals at discrete frequency steps across 4 GHz bandwidths centered at four frequencies: 20, 44, 95, and 140 GHz. The sampled data would be stored for later processing to calculate the distance from the spacecraft surface to the critical electron densities versus time. Four stepped PM CW transmitter receivers were located behind the thermal protection system of the spacecraft with horn antennas radiating and receiving through an insulating tile. Techniques were developed to deal with interference, including multiple reflections and resonance effects, resulting from the antenna configuration and operating environment.

The second flight of the Spacelab grille spectrometer, which took advantage of the favorable timeline and of the extra day to perform more than 65 successful solar occultation runs, is addressed. The purpose of the Atlas mission, flown onboard the American Space Shuttle, was to study the evolution of atmospheric properties over an entire solar cycle. The grille spectrometer measured the vertical concentration profiles of trace gases. It succeeded in obtaining spectra pertinent to its ten target molecules in the full range of altitudes available to the solar infrared occultation technique. These ten molecules are H2O, CO, CO2, CH4, NO, NO2, N2O, HCl, HF, and O3. A preliminary analysis of an HCl observation is presented showing no significant change of upper atmospheric hydrogen chloride in comparison with previous data. ESA

(NASA-TM-105706; E-8100; NAS 1.15:105706) Avail: CASI HC A14/MF A03

This report was prepared by members of the Fuels, Materials and Related Technologies Panel, with assistance from a number of industry observers as well as laboratory colleagues of the panel members. It represents a consensus view of the panel members. This report was not subjected to a thorough review by DOE, NASA or DoD, and the opinions expressed should not be construed to represent the official position of these organizations, individually or jointly. Topics addressed include: requirement for fuels and materials development for nuclear thermal propulsion (NTP) and nuclear electric propulsion (NEP); overview of proposed concepts; fuels technology development plan; materials technology development plan; other reactor technology development; and fuels and materials requirements for advanced propulsion concepts.

ROCKET MOTOR PLUME TECHNOLOGY [L'ETUDE DES JETS DES MOTEURS-FUSEES]

Jun. 1993 196 p In ENGLISH and FRENCH Lecture series held in Neubiberg, Germany, 7-8 Jun. 1993 and in Ankara, Turkey, 10-11 Jun. 1993

(AGARD-LS-188; ISBN-92-835-0713-4) Copyright Avail: CASI HC A09/MF A03

Requirements for missile guidance and stealth properties are changing and becoming more stringent. There is no up-to-date synthesis relating rocket motor plume properties to these new requirements. The work performed and recently finished within PEP WG 21 formed the basis for this Lecture Series. The scope of the Lecture Series will be rocket motor exhaust products and plumes in all their aspects. Plume properties are addressed and methods of numerical simulation and experimental assessment described. Specifically, plume structure, after-burning phenomena, primary and secondary smoke, plume radiation signatures, and plume microwave interactions are described in detail. Operational aspects linked to these topics discuss how rocket plumes influence missile detection, guidance, and tracking. Ways in which plumes may be modified to reduce or eliminate this influence are suggested. For individual titles, see N94-15218 through N94-15223.

PLUME PRIMARY SMOKE

J. C. Chastenet *In* AGARD, Rocket Motor Plume Technology Jun. 1993 19 p (For primary document see N94-15217 03-20)

Copyright Avail: CASI HC A03/MF A03

The exhaust from a solid propellant rocket motor usually contains condensed species. These particles, also called 'Primary Smoke', are often prejudicial to missile detectability and to the guidance system. To avoid operational problems it is necessary to know and quantify the effects of particles on all aspects of missile deployment. A brief description of the origin of the primary smoke is given. It continues with details of the interaction between particles and light as function of both particles and light properties (nature, size, wavelength, etc). The effects of particles on plume visibility, attenuation of an optical beam propagated through the

plume and the contribution of particles on optical signatures of the plume are also described. Finally, various methods used in NATO countries to quantify the primary smoke effects are discussed. Author (revised)

Current requirements for missile systems increasingly stress the need for stealth capability. For the majority of missile systems and missions, the exhaust plume is likely to be the major contributor to overall missile signature, especially considering the recent developments in low emission and low Radar Cross Section coatings for motor bodies. This implies the need for the lowest possible rocket exhaust signature over a wide range of frequencies from the UV through visible and IR to microwave and radio frequencies. The choice of propellant type, Double Base; Composite etc, plays a significant part in determining the exhaust signature of the rocket motor as does the selection of inert materials for liners, inhibitors, and nozzles. It is also possible with certain propellants to incorporate additives which reduce exhaust signature either by modifying the chemistry or the afterburning plume or more significantly by suppressing secondary combustion and hence dramatically reducing plume temperature. The feasibility of plume signature control on the various missions envisaged by the missile designer is considered. The choice of propellant type and hardware components to give low signature is discussed together with performance implications. Signature reduction results obtained over a wide range of frequencies are also presented. Author (revised)

The open literature on secondary smoke formation, prediction, and classification is briefly reviewed. This review was limited to the open literature in order to promote the widest possible discussion within the AGARD engineering community. The recently completed PEP WG 21 proposal for smoke classification is presented. Secondary smoke is defined and the physics of condensation of vapor onto droplets is reviewed. The basis for the existing droplet condensation models is discussed and the existing methodology for predicting secondary smoke light attenuation and scattering is presented. Test data taken to establish the initial conditions for heterogeneous nucleation in rocket plumes is presented. Comparisons between secondary smoke predictions and flight data are presented. The state of the art of secondary smoke modeling is discussed and suggestions are made for improvements. Author

ROCKET MOTOR PLUME FLOWFIELDS: PHENOMENOLOGY AND SIMULATION
Sanford M. Dash *In* AGARD, Rocket Motor Plume Technology Jun. 1993 30 p (For primary document see N94-15217 03-20)
Copyright Avail: CASI HC A03/MF A03

The varied processes occurring in rocket motor exhaust plumes and methodology for simulating these processes are described. Rocket motor plumes contain shock waves due to under/overexpansion; the exhaust mixes with the external stream in a highly compressible turbulent environment; unburnt products of combustion after-burn strongly at lower altitudes; and solid propellant plumes contain particulates which are generally out of equilibrium with the gas-phase exhaust. Earlier methodology simulated the varied processes using boundary layer type coupling. Current methods implement solutions of the full or reduced (parabolized) Navier-Stokes equations where all fluid dynamic and thermochemical processes are strongly coupled. Earlier methodology are reviewed briefly while the status of current methods is addressed in greater detail. Author (revised)

MICROWAVE PROPERTIES AND SYSTEMS OVERVIEW **c32**
Ronald Lawrence *In* AGARD, Rocket Motor Plume Technology Jun. 1993 35 p (For primary document see N94-15217 03-20)
Copyright Avail: CASI HC A03/MF A03

Of particular significance to the operational success of a missile using microwave communications is the interference introduced by the rocket exhaust plume. As a hot and turbulent gas stream the exhaust has electrical properties that can seriously degrade guidance and tracking. Also present is the potential for missile detection offered by energy scattered from microwave signals impinging upon the plume to present a radar cross section, and an exhaust signature from inherent emission sources within the plume. This paper presented in AGARD Lecture Series 188, follows from AGARD Advisory Report 287 submitted by Propulsion and Energetics Panel Working Group 21 entitled 'Terminology and Assessment Methods of Solid Propellant Rocket Exhaust Signatures.' It provides a description of microwave propagation through a rocket exhaust, the cause of signal attenuation, and the generation of phase and amplitude sideband noise. Consideration is given to the effects of missile flight velocity and altitude. Diffraction and refraction processes are discussed, particularly in relation to plumes containing high density concentrations of free electrons. Radiation sources, mainly at millimetric wavelengths, are included together with signature implications. The effects of exhaust interference with communications is examined from a system point of view and some methods of relief from the interference are considered. Author (revised)

PLUME RADIATION **c32**
R. Dirscherl *In* AGARD, Rocket Motor Plume Technology Jun. 1993 47 p (For primary document see N94-15217 03-20)
Copyright Avail: CASI HC A03/MF A03

The electromagnetic radiation originating from the exhaust plume of tactical missile motors is of outstanding importance for military system designers. Both missile- and countermeasure engineer rely on the knowledge of plume radiation properties, be it for guidance/interference control or for passive detection of adversary missiles. To allow access to plume radiation properties, they are characterized with respect to the radiation producing mechanisms like afterburning, its chemical constituents, and reactions as well as particle radiation. A classification of plume spectral emissivity regions is given due to the constraints imposed by available sensor technology and atmospheric propagation windows. Additionally assessment methods are presented that allow a common and general grouping of rocket motor properties into various categories. These methods describe state of the art experimental evaluation techniques as well as calculation codes that are most commonly used by developers of NATO countries. Dominant aspects influencing plume radiation are discussed and a standardized test technique is proposed for the assessment of plume radiation properties that include prediction procedures. These recommendations on terminology and assessment methods should be common to all employers of plume radiation. Special emphasis is put on the omnipresent need for self-protection by the passive detection of plume radiation in the ultraviolet (UV) and infrared (IR) spectral band. Author

SPDE/SPRE FINAL SUMMARY REPORT

George Dochat Sep. 1993 98 p
(Contract NAS3-23883; RTOP 590-13-11)
(NASA-CR-187086; E-8126; NAS 1.26:187086) Avail: CASI HC A05/MF A02

Mechanical Technology Incorporated (MTI) performed acceptance testing on the Space Power Research Engine (SPRE), which demonstrated satisfactory operation and sufficient reliability for delivery to NASA Lewis Research Center. The unit produced 13.5 kW PV power with an efficiency of 22 percent versus design goals of 28.8 kW PV power and efficiency of 28 percent. Maximum electric power was only 8 kWe due to lower alternator efficiency. One of the major shortcomings of the SPRE was linear alternator efficiency, which was only 70 percent compared to a design value of 90 percent. It was determined from static tests that the major cause for the efficiency shortfall was the location of the magnetic structure surrounding the linear alternator. Testing of an alternator configuration without a surrounding magnetic structure on a linear dynamometer confirmed earlier static test results. Linear alternator efficiency improved from 70 percent to over 90 percent. Testing of the MTI SPRE was also performed with hydrodynamic bearings and achieved full-stroke, stable operation. This testing indicated that hydrodynamic bearings may be useful in free piston Stirling engines. An important factor in achieving stable operation at design stroke was isolating a portion of the bearing length from the engine pressure variations. In addition, the heat pipe heater head design indicates that integration of a Stirling engine with a heat source can be performed via heat pipes. This design provides a baseline against which alternative designs can be measured. Author (revised)

NUCLEAR ROCKET PLUME STUDIES Final Report, Aug. 1991 - Jul. 1993
Daniel Hastings 5 May 1993 92 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0415-91)
(AD-A267154; AFOSR-93-0461TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A description and detailed computational analysis of a vortex cleaning system designed to remove radioactive material from the plumes of nuclear rockets is included. The proposed system is designed to remove both particulates and radioactive gaseous material from the plume. A two part computational model is used to examine the system's ability to remove particulates, and the results indicate that under some conditions, the system can remove over 99% of the particles in the flow. Two critical parameters which govern the effectiveness of the system are identified and the information necessary to estimate cleaning efficiencies for particles of known sizes and densities is provided. A simple steady analytical solution is also developed to examine the system's ability to remove gaseous radioactive material. This analysis, while inconclusive, suggests that the swirl rates necessary to achieve useful efficiencies are too high to be achieved in any practical manner. Therefore, this system is probably not suitable for use, with gaseous radioactive material. It was concluded that the system can cause negligible specific impulse losses, though there may be a substantial mass penalty associated with its use. DTIC

SHOCK-FREE SUPERSONIC ELLIPTIC NOZZLES AND METHOD OF FORMING SAME Patent Application
John M. Seiner, inventor (to NASA) and Roy S. Baty, inventor (to NASA) 19 Jul. 1993 20 p
(NASA-Case-LAR-14054-1; NAS 1.71:LAR-14054-1; US-Patent-Appl-SN-095563) Avail: CASI HC A03/MF A01

A method of forming a shock-free supersonic elliptic nozzle, in which the nozzle to be designed is divided into three sections, a circular-to-elliptic section which begins at a circular nozzle inlet, an elliptic subsonic section downstream from the circular-to-elliptic section, and a supersonic section downstream from the elliptic subsonic section is described. The maximum and minimum radii for each axial point in the circular-to-elliptic section and the elliptic subsonic section are then separately determined, the maximum and minimum radii being the radii for the widest part of an elliptic cross-section and the narrowest part of the elliptic cross-section, respectively. The maximum and minimum radii for each axial point in the supersonic section are determined based on the Method of Characteristics. Then, each of the three sections are based on the maximum and minimum radii for each axial point in the section. The resulting nozzle is acoustically superior. NASA

FUNDAMENTAL STUDIES OF ROCKET COMBUSTION CHEMISTRY AND COMBUSTION INSTABILITY Final Technical Report, 1989 - 1992
Melvyn C. Branch, John W. Daily, Shankar Mahalingam, and Gregory J. Fiechtner Feb. 1993 34 p
(Grant AF-AFOSR-0121-90)
(AD-A266248; CCR-93-01; AFOSR-93-0432TR) Avail: CASI HC A03/MF A01

This report provides a summary of results obtained over the past year in fundamental studies of the chemistry of solid rocket combustion and of combustion instability in liquid rocket combustion. A coordinated research program has been initiated to study separate aspects of the complex multidimensional, multiphase, and multicomponent reacting flow characteristic of rocket combustion. The focus of the combustion chemistry studies is on flame reactions of gas phase species formed as decomposition products near the surface of the propellant. These flames typically involve a variety of fuel species and nitrogen oxides as oxidizers. The focus of the combustion instability studies is the effect of atomization and vaporization processes on the oscillatory conditions characteristic of combustion instability. The research objectives, progress, and research in progress in each of these areas are summarized in the report. DTIC

LUNAR LANDER AND RETURN PROPULSION SYSTEM TRADE STUDY

Eric A. Hurlbert, Robert Moreland, Gerald B. Sanders, Edward A. Robertson, David Amidei, and John Mulholland et al Aug. 1993 202 p
(NASA-TP-3388; S-728; NAS 1.60:3388) Avail: CASI HC A10/MF A03

This trade study was initiated at NASA/JSC in May 1992 to develop and evaluate main propulsion system alternatives to the reference First Lunar Outpost (FLO) lander and return-stage transportation system concept. Thirteen alternative configurations were developed to explore the impacts of various combinations of return stage propellants, using either pressure or pump-fed propulsion systems and various staging options. Besides two-stage vehicle concepts, the merits of single-stage and stage-and-a-half options were also assessed in combination with high-performance liquid oxygen and liquid hydrogen propellants. Configurations using an integrated modular cryogenic engine were developed to assess potential improvements in packaging efficiency, mass performance, and system reliability compared to non-modular cryogenic designs. The selection process to evaluate the various designs was the analytic hierarchy process. The trade study showed that a pressure-fed MMH/N2O4 return stage and RL10-based lander stage is the best option for a 1999 launch. While results of this study are tailored to FLO needs, the design date, criteria, and selection methodology are applicable to the design of other crewed lunar landing and return vehicles. Author

(NASA-CR-191645; NAS 1.26:191645; CS91-TR-JSC-017) Avail: CASI HC A03/MF A01; 5 functional color pages

On 1 May 1991, the Nimbus 6 second stage Delta Rocket Body experienced a major breakup at an altitude of approximately 1,100 km. There were numerous pieces left in long-lived orbits, adding to the long-term hazard in this orbital regime already present from previous Delta Rocket Body explosions. The assessed cause of the event is an accidental explosion of the Delta second stage by documented processes experienced by other similar Delta second stages. Various aspects of the event are discussed. Author

SPACE NUCLEAR FACILITY TEST CAPABILITY AT THE BAIKAL-1 AND IGR SITES SEMIPALATINSK-21, KAZAKHSTAN
T. J. Hill, M. L. Stanley, and J. S. Martinell Jan. 1993 85 p Presented at the Nuclear Power Engineering in Space Nuclear Rocket Engines, Kazakhstan, Russia, 22-26 Sep. 1992
(Contract DE-AC07-76ID-01570)
(DE93-011662; DOE/FTR-93011662; CONF-9209177-Summ) Avail: CASI HC A05/MF A01 (US Sales Only)

The International Space Technology Assessment Program was established 1/19/92 to take advantage of the availability of Russian space technology and hardware. DOE had two delegations visit CIS and assess its space nuclear power and propulsion technologies. The visit coincided with the Conference on Nuclear Power Engineering in Space Nuclear Rocket Engines at Semipalatinsk-21 (Kurchatov, Kazakhstan) on Sept. 22-25, 1992. Reactor facilities assessed in Semipalatinski-21 included the IVG-1 reactor (a nuclear furnace, which has been modified and now called IVG-1M), the RA reactor, and the Impulse Graphite Reactor (IGR), the CIS version of TREAT. Although the reactor facilities are being maintained satisfactorily, the support infrastructure appears to be degrading. The group assessment is based on two half-day tours of the Baikals-1 test facility and a brief (2 hr) tour of IGR; because of limited time and the large size of the tour group, it was impossible to obtain answers to all prepared questions. Potential benefit is that CIS fuels and facilities may permit USA to conduct a lower priced space nuclear propulsion program while achieving higher performance capability faster, and immediate access to test facilities that cannot be available in this country for 5 years. Information needs to be obtained about available data acquisition capability, accuracy, frequency response, and number of channels. Potential areas of interest with broad application in the U.S. nuclear industry are listed. DOE

SPACE SHUTTLE MAIN ENGINE. NASA HAS NOT EVALUATED THE ALTERNATE FUEL TURBOPUMP COSTS AND BENEFITS. REPORT TO THE ADMINISTRATOR OF THE NATIONAL AERONAUTICS AND SPACE ADMINISTRATION
Oct. 1993 15 p
(GAO/NSIAD-94-54; B-255456) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

NASA's plans to develop an alternate high pressure fuel turbopump for the Space Shuttle's main engines were assessed by the General Accounting Office as a part of the evaluation of the Space Shuttle Safety and Obsolescence Upgrade program. The objective was to determine whether NASA has adequately analyzed cost, performance, and benefits that are expected to result from this program in comparison to other alternatives before resuming development of the alternate pump, which was suspended in 1992. The alternate fuel pump is one of five improvements being developed or planned to significantly enhance safety margins of the engines. Derived from text

HOLLOW CATHODE HEATER DEVELOPMENT FOR THE SPACE STATION PLASMA CONTACTOR Final Report
George C. Soulas Oct. 1993 14 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, DGLR, and JSASS
(Contract NAS3-25266; RTOP 474-46-10)
(NASA-CR-191131; E-7846; NAS 1.26:191131) Avail: CASI HC A03/MF A01

A hollow cathode-based plasma contactor has been selected for use on the Space Station. During the operation of the plasma contactor, the hollow cathode heater will endure approximately 12000 thermal cycles. Since a hollow cathode heater failure would result in a plasma contactor failure, a hollow cathode heater development program was established to produce a reliable heater design. The development program includes the heater design, process documents for both heater fabrication and assembly, and heater testing. The heater design was a modification of a sheathed ion thruster cathode heater. Three heaters have been tested to date using direct current power supplies. Performance testing was conducted to determine input current and power requirements for achieving activation and ignition temperatures, single unit operational repeatability, and unit-to-unit operational repeatability. Comparisons of performance testing data at the ignition input current level for the three heaters show the unit-to-unit repeatability of input power and tube temperature near the cathode tip to be within 3.5 W and 44 degrees C, respectively. Cyclic testing was then conducted to evaluate reliability under thermal cycling. The first heater, although damaged during assembly, completed 5985 ignition cycles before failing. Two additional heaters were subsequently fabricated and have completed 3178 cycles to date in an on-going test. Author

DEVELOPMENT AND ANALYSIS OF STARTUP STRATEGIES FOR PARTICLE BED NUCLEAR ROCKET ENGINE M.S. Thesis
David E. Suzuki Jun. 1993 104 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267949; AFIT/CI/CIA-93-088) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The particle bed reactor (PBR) nuclear thermal propulsion rocket engine concept is the focus of the Air Force's Space Nuclear Thermal Propulsion program. While much progress has been made in developing the concept, several technical issues remain. Perhaps foremost among these concerns is the issue of flow stability through the porous, heated bed of fuel particles. There are two complementary technical issues associated with this concern: the identification of the flow stability boundary and the design of the engine controller to maintain stable operation. This thesis examines a portion of the latter issue which has yet to be addressed in detail. Specifically, it develops and analyzes general engine system startup strategies which maintain stable flow through the PBR fuel elements while reaching the design conditions as quickly as possible. The PBR engine studies are conducted using a computer model of a representative particle bed reactor and engine system. The computer program utilized is an augmented version of SAFSIM, an existing nuclear thermal propulsion modeling code; the augmentation, dubbed SAFSIM+, was developed by the author and provides a more complete engine system modeling tool. This is the final report for the actuator bracket/lug fracture mechanics qualification test. The test plan (CTP-0071) outlined a two-phase test program designed to answer questions about the fracture criticality of the redesigned solid rocket motor (RSRM) nozzle actuator bracket. An analysis conducted using the NASA/FLAGRO fracture mechanics computer program indicated that the actuator bracket might be a fracture critical component. In the NASA/FLAGRO analysis, a simple lug model was used to represent the actuator bracket. It was calculated that the bracket would fracture if subjected to an actuator stall load in the presence of a 0.10 in. corner crack at the actuator attachment hole. The 0.10 in. crack size corresponds to the nondestructive inspection detectability limit for the actuator bracket. The inspection method used is the dye penetrant method. The actuator stall load (103,424 lb) is the maximum load which the actuator bracket is required to withstand during motor operation. This testing was designed to establish the accuracy of the analytical model and to directly determine whether the actuator bracket is capable of meeting fracture mechanics safe-life requirements. ADVANCED TRANSPORTATION SYSTEM STUDIES TECHNICAL AREA 3: ALTERNATE PROPULSION SUBSYSTEM CONCEPTS, VOLUME 2 Interim Final Report, 6 Apr. 1992 - 5 Apr. 1993
Daniel Levak Apr. 1993 15 p
(Contract NAS8-39210)
(NASA-CR-193863; NAS 1.26:193863; RI/RD93-123-2) Avail: CASI HC A03/MF A01

The Alternate Propulsion Subsystem Concepts contract had five tasks defined for the first year. The tasks were: F-1A Restart Study, J-2S Restart Study, Propulsion Database Development, Space Shuttle Main Engine (SSME) Upper Stage Use, and CER's for Liquid Propellant Rocket Engines. The detailed study results, with the data to support the conclusions from various analyses, are being reported as a series of five separate Final Task Reports. Consequently, this volume only reports the required programmatic information concerning Computer Aided Design Documentation, and New Technology Reports. A detailed Executive Summary, covering all the tasks, is also available as Volume 1.

ADVANCED TRANSPORTATION SYSTEM STUDIES TECHNICAL AREA 3: ALTERNATE PROPULSION SUBSYSTEM CONCEPTS, VOLUME 3 Interim Final Report, 6 Apr. 1992 - 5 Apr. 1993
Daniel Levak Apr. 1993 40 p
(Contract NAS8-39210)
(NASA-CR-193864; NAS 1.26:193864; RI/RD93-123-3) Avail: CASI HC A03/MF A01

The objective of this contract was to provide definition of alternate propulsion systems for both earth-to-orbit (ETO) and in-space vehicles (upper stages and space transfer vehicles). For such propulsion systems, technical data to describe performance, weight, dimensions, etc. was provided along with programmatic information such as cost, schedule, needed facilities, etc. Advanced technology and advanced development needs were determined and provided. This volume separately presents the various program cost estimates that were generated under three tasks: the F-1A Restart Task, the J-2S Restart Task, and the SSME Upper Stage Use Task. The conclusions, technical results, and the program cost estimates are described in more detail in Volume 1 - Executive Summary and in individual Final Task Reports. Author

ADVANCED TRANSPORTATION SYSTEM STUDIES TECHNICAL AREA 3: ALTERNATE PROPULSION SYSTEM CONCEPTS. SSME UPPER STAGE USE Task Final Report, May 1992 - Apr. 1993
Eric Strangeland and Daniel Levak Apr. 1993 145 p
(Contract NAS8-39210)
(NASA-CR-193865; NAS 1.26:193865) Avail: CASI HC A07/MF A02

The main objective was to determine viable methods for starting the Space Shuttle Main Engine (SSME) in an altitude environment and restarting it in an orbit environment with minimum changes in utilization of the engine system or hardware. The study concluded that the use of the SSME in an upper stage is feasible with minimal changes to the engine systems. The altitude start case requires only a change in the valve sequencing during start and reorificing of the ASI lines. Inlet pressures can be moderately low at 40 psia for the LOX and 32 psia for the H2. The orbital restart case adds the need to recirculate propellant and thermal control paint (to keep the turbomachinery inlets cold to minimize the tank pressures needed), and the need to heat two small components (to maintain acceptable mixture ratios during the early part of the start). These actions allow start anytime after approximately 120 minutes. Earlier starts (approximately one hour) are also possible but would require additional component heating for mixture ratio control during the early portion of the start sequence.

SRB THERMAL CURTAIN DESIGN SUPPORT Final Report
Carl A. Dixon Dec. 1991 42 p Sponsored by U.S. Polymeric B.P. Chemicals, Santa Anna, CA

(Contract NAS8-38261)
(NASA-CR-193857; SRI-MME-92-564-7079; NAS 1.26:193857) Avail: CASI HC A03/MF A01

The objective of the program during this time period was to evaluate candidate materials that could be used to design an improved Solid Rocket Motor (SRM) Aft Skirt Thermal Curtain (ASTC). The ASTC is a flexible, high temperature, cloth and insulation composite that is used to protect the hardware located inside the aft skirt of the shuttle solid rocket booster. The current ASTC consists of nine layers of insulating materials and is 2.58 inches thick. The ASTC is made up of twenty four segments. The segments are hand sewn together during installation on the aft skirt. The weight of the current ASTC is approximated at about six hundred pounds. This weight does not include the weight of the mounting hardware and ties required to install the twenty four ASTC segments (which is significant). The current effort entailed measuring the thermophysical properties of six candidate materials (quartz, S glass, and Kevlar woven into nominal 0.25 inch thick layers by angle interlock and polar-weave) and then using these properties in a computer program to predict the thermal performance of various curtain configurations subjected to an SRM heat flux.

FLIGHT 20 (STS-45) POLYSULFIDE GAS PATH INVESTIGATION Final Report
Rey C. Bjorkman, Charles W. Bown, Scott D. Smith, Jerry L. Walters, Suresh B. Kulkarni, Roger V. Cook, David A. Sebahar, Craig S. Walker, M. Reed Haddock, and Robert E. Lindstrom Jul. 1992 182 p
(Contract NAS8-38100)
(NASA-CR-193861; TRW-63941; NAS 1.26:193861; Publ-922023) Avail: CASI HC A09/MF A02

This report documents the results of the investigation into causes of gas paths on the 20A and 20B case-to-nozzle joints on STS-42. The investigation was conducted by the Investigation Board appointed by the senior vice president and general manager of Space Operations, Mr. R. E. Lindstrom, on 7 Feb. 1992. The probability of gas path occurrence in the nozzle-to-case-joint polysulfide had been identified during joint redesign. However, actual flight gas path incidence has been limited to RSRM-11 and the 20A and 20B segments. The blow-by condition on the 20A segment was a first time occurrence which was a special concern. The investigation covered all technical aspects associated with the gas path and blow-by conditions: materials and processing history, design requirements and as-built compliance to the design, thermal and structural analyses, computer modeling, and laboratory experimentation with the materials involved. The investigation was coordinated with Mr. Ken Jones at NASA Marshall in bi-weekly teleconferences. The Board also supported Dr. James C. Blair's independent NASA investigation team by providing copies of collected data, conducting requested analyses, and supporting several all-day teleconferences to provide understanding and resolve issues. The Dr. Blair support requirement was successfully concluded on 4 Mar. 1992.

The Solar Dynamic (SD) Ground Test Demonstration (GTD) program demonstrates the availability of SD technologies in a simulated space environment at the NASA Lewis Research Center (LeRC) vacuum facility. An aerospace industry/ government team is working together to design, fabricate, build, and test a complete SD system. This paper reviews the goals and status of the SD GTD program. A description of the SD system includes key design features of the system, subsystems, and components as reported at the Critical Design Review (CDR).

ASRM NOZZLE THERMAL ANALYSIS Final Report
Forrest Strobel and Belinda King Nov. 1993 101 p
(Contract NAS8-39611)
(NASA-CR-194672; NAS 1.26:194672; AEROTHERM-FR-7186-93-15)
Avail: CASI HC A06/MF A02

This report describes results from the nozzle thermal analysis contract which has been performed to support NASA/Marshall Space Flight Center in the development of the Advanced Solid Rocket Motor (ASRM). The emphasis of this study has been directed to four potential problem areas of the nozzle. These areas are the submerged nozzle region containing the flex seal, the nozzle entrance region, the material interface region in the nozzle exit cone, and the aft region of the exit cone. This study was limited throughout by inadequate material response models, especially for the polyisoprene flex seal and the low density carbon phenolic used in the exit cone. Thermal response and particle erosion calculations were performed for each of the potential problem areas. Results from these studies showed excessive erosion (large negative safety margins) to occur in the flex seal and nozzle entrance regions. The exit cone was found to be marginally adequate (near zero safety margins) and the material interface region was found not to be a problem.

HIGH POWER STEADY STATE MPD THRUSTERS Final Report, Sep. 1989 - Aug. 1991
Monika Auweter-Kurtz, Harald Habiger, Helmut Kurtz, Herbert Schrade, and Cristian Sleziona Apr. 1993 56 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0535-89)
(AD-A267277; PL-TR-92-3054) Avail: CASI HC A04

At the Institut fuer Raumfahrtsysteme (IRS) rotation symmetric magnetoplasmadynamic thrusters with self induced magnetic fields are investigated at high current levels in a steady state operation mode. MPD thrusters with different geometrics were compared, and the influence of mass flow rate and power input on the operating conditions of the thrusters explored. By optical and probe measurements, a systematic investigation of the plasma plume has been started. The investigation of the various instabilities of the arc and the plasma flow appearing at high power levels was continued. The computer code development for the geometry optimization of continuous self-field MPD thrusters, running with argon, was modified by considering higher degrees of ionization, which showed better agreement with the experiment.

COMPUTATIONAL ANALYSIS OF VARIABLE THRUST ENGINE (VTE) PERFORMANCE Final Report, 21 Apr. 1989 - Jan. 1993
M. G. Giridharan, A. Krishnan, and A. J. Przekwas Feb. 1993 95 p
(Contract NAS8-37196)
(NASA-CR-193852; CFDRC-4075/3; NAS 1.26:193852) Avail: CASI HC A05/MF A01

The Variable Thrust Engine (VTE) of the Orbital Maneuvering Vehicle (OMV) uses a hypergolic propellant combination of Monomethyl Hydrazine (MMH) and Nitrogen Tetroxide (NTO) as fuel and oxidizer, respectively. The performance of the VTE depends on a number of complex interacting phenomena such as atomization, spray dynamics, vaporization, turbulent mixing, convective/radiative heat transfer, and hypergolic combustion. This study involved the development of a comprehensive numerical methodology

to facilitate detailed analysis of the VTE. An existing Computational Fluid Dynamics (CFD) code was extensively modified to include the following models: a two-liquid, two-phase Eulerian-Lagrangian spray model; a chemical equilibrium model; and a discrete ordinate radiation heat transfer model. The modified code was used to conduct a series of simulations to assess the effects of various physical phenomena and boundary conditions on the VTE performance. The details of the models and the results of the simulations are presented. Author (revised)

FLOW INSTABILITY TESTS FOR A PARTICLE BED REACTOR NUCLEAR THERMAL ROCKET FUEL ELEMENT M.S. Thesis
Timothy J. Lawrence May 1993 345 p
(AD-A268012; AFIT/CI/CIA-93-079) Avail: CASI HC A15/MF A03

Recent analyses have focused on the flow stability characteristics of a particle bed reactor (PBR). These laminar flow instabilities may exist in reactors with parallel paths and are caused by the heating of the gas at low Reynolds numbers. This phenomena can be described as follows: several parallel channels are connected at the plenum regions and are stabilized by some inlet temperature and pressure; a perturbation in one channel causes the temperature to rise and increases the gas viscosity and reduces the gas density; the pressure drop is fixed by the plenum regions, therefore, the mass flow rate in the channel would decrease; the decrease in flow reduces the ability to remove the energy added and the temperature increases; and finally, this process could continue until the fuel element fails. Several analyses based on different methods have derived similar curves to show that these instabilities may exist at low Reynolds numbers and high phi's ((Tfinal Tinitial)/Tinitial). These analyses need to be experimentally verified. DTIC

SPACE STATION FREEDOM ELECTRICAL PERFORMANCE MODEL
Jeffrey S. Hojnicki, Robert D. Green, Thomas W. Kerslake, David B. McKissock, and Jeffrey J. Trudell Nov. 1993 9 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993; sponsored by American Chemical Society
(RTOP 474-12-10)
(NASA-TM-106395; E-8220; NAS 1.15:106395) Avail: CASI HC A02/MF A01

The baseline Space Station Freedom electric power system (EPS) employs photovoltaic (PV) arrays and nickel hydrogen (NiH2) batteries to supply power to housekeeping and user electrical loads via a direct current (dc) distribution system. The EPS was originally designed for an operating life of 30 years through orbital replacement of components. As the design and development of the EPS continues, accurate EPS performance predictions are needed to assess design options, operating scenarios, and resource allocations. To meet these needs, NASA Lewis Research Center (LeRC) has, over a 10 year period, developed SPACE (Station Power Analysis for Capability Evaluation), a computer code designed to predict EPS performance. This paper describes SPACE, its functionality, and its capabilities. Author (revised)

HEAT TRANSFER PARAMETRIC SYSTEM IDENTIFICATION M.S. Thesis
Gregory K. Parker Jun. 1993 116 p
(AD-A268525) Avail: CASI HC A06/MF A02

This work describes the development of a computer based model that would allow for determination of the transient thermal response characteristics of jet vanes of any size. The model used a thermal lump approach method, considering only conductive and convective heat transfer properties. A constrained optimizer was used to adjust the unknown variables until an adequate match was achieved between the calculated values of the energy balance equations and the experimental data obtained from test firings of a rocket motor. The full scale modeling results were compared to previous quarter scale models in an attempt to determine the applicability of the quarter scale results to full scale vanes. It was determined that the quarter scale model did not provide an accurate representation of the heat transfer process in larger scale vanes, although the full scale model provided a sufficient representation of the thermal response of the jet vane. APPLICATION OF A NEPTUNE PROPULSION CONCEPT TO A MANNED MARS EXCURSION M.S. Thesis
Charles J. Finley Apr. 1993 135 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268053; AFIT/CI/CIA-93-111) Avail: CASI HC A07

NEPTUNE is a multimegawatt electric propulsion system. It uses a proven compact nuclear thermal rocket, NERVA, in a closed cycle with a magnetohydrodynamic (MHD) generator to power a magnetoplasmadynamic (MPD) thruster. This thesis defines constraints on an externally sourced propulsion system intended to carry out a manned Martian excursion. It assesses NEPTUNE's ability to conform to these constraints. Because an unmodified NEPTUNE system is too large, the thesis develops modifications to the system which reduce its size. The result is a far less proven, but more useful derivative of the unmodified NEPTUNE system. DTIC

Avail: CASI HC A03/MF A01

The tribological characteristics of ceramics sliding on ceramics are compared to those of ceramics sliding on a nickel based turbine alloy. The friction and wear of oxide ceramics and silicon-based ceramics in air at temperatures from room ambient to 900 C (in a few cases to 1200 C) were measured for a hemispherically-tipped pin on a flat sliding contact geometry. In general, especially at high temperature, friction and wear were lower for ceramic/metal combinations than for ceramic/ceramic combinations. The better tribological performance for ceramic/metal combinations is attributed primarily to the lubricious nature of the oxidized surface of the metal. Author (revised)

SYNTHESIS, REACTIVITY, AND CHARACTERIZATION OF (-HEXACARBOCYCLIC) MANGANESE DICARBONYL COMPLEXES WITH SULFUR AND PHOSPHORUS LIGANDS Ph.D. Thesis
Jeffrey L. Moler May 1993 271 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267592; AFIT/CI/CIA-93-012D) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A series of (eta(exp 5) pentamethyl benzyl) manganese dicarbonyl phosphite complexes have been synthesized. Manganese coordinated phosphites react with the exocyclic methylene of the coordinated pentamethyl benzyl ligand generating either benzyne or a carbene, an eta(exp 6) hexaalkyl benzene, and dialkyl- or diaryl phosphonate complexes. Their decomposition to phosphonates was observed under reduced pressure or in the presence of olefins. Benzyne, from the triphenyl phosphite complexes was observed indirectly through the formation of diphenylene. The production of methylene carbenes was observed by the formation of ethene and cyclopropanes. The generation of olefins or cyclopropanes indicated that ethylidene was produced. DTIC

THERMAL STRESSES OF A TRIMATERIAL MEDIUM IN A NONUNIFORM TEMPERATURE FIELD M.S. Thesis
Michael J. Neibert Mar. 1993 108 p
(AD-A267243) Avail: CASI HC A06/MF A02

The objective of this investigation was to conduct a parametric study of the effect of a nonuniform temperature field on the system behavior of a trilayered medium. In particular, the resulting shear and normal stresses along the media interfaces are analyzed. A finite element model utilizing a recently developed element which provides for both axial and lateral displacement continuity is employed. First, the effect of the material properties, that is, Young's Modulus and coefficient of thermal expansion, is examined. Then, the effect of the geometric properties, that is, length and thickness dimensions of the midlayer, is analyzed. Finally, a study of the effect of a nonuniform temperature field on the trimaterial medium is conducted. DTIC

THE EFFECT OF PLASMA TREATMENT ON INTERFACIAL BOND CHARACTERISTICS OF KEVLAR/EPOXY LAMINATES AS MEASURED BY T-PEEL TESTS Final Report
Rachel A. Michaud and Joey L. Mead May 1993 13 p
(AD-A266920; ARL-TR-141) Avail: CASI HC A03/MF A01

Composite materials are used in a wide variety of applications where their anisotropic properties allow the material to be tailored for each application. Unfortunately, aramid fiber composites may have limited applications due to poor transverse properties. These poor transverse properties are the result of weak interfacial bonding. Improvement of the interfacial bond strength has been an area of active research. Plasma treatment is one method that can be used to modify the surface of a fiber in an effort to improve the fiber-matrix adhesion. Kevlar/epoxy laminates were peel-tested (T-peel) to study the effect of plasma treatment on the interfacial properties. The T-peel results indicate that ammonia plasma treatment improves the interfacial bond strength of Kevlar/epoxy composites, increasing the T-peel strengths by approximately 30%. DTIC

INELASTIC DEFORMATION OF METAL MATRIX COMPOSITES Final Report
C. J. Lissenden, C. T. Herakovich, and M-J. Pindera Sep. 1993 109 p
(Grant NAG1-745; RTOP 506-73-43-03)
(NASA-CR-191522; AM-93-03; NAS 1.26:191522) Avail: CASI HC A06/MF A02

A theoretical model capable of predicting the thermomechanical response of continuously reinforced metal matrix composite laminates subjected to multiaxial loading was developed. A micromechanical model is used in conjunction with nonlinear lamination theory to determine inelastic laminae response. Matrix viscoplasticity, residual stresses, and damage to the fiber/matrix interfacial zone are explicitly included in the model. The representative cell of the micromechanical model is considered to be in a state of generalized plane strain, enabling a quasi two-dimensional analysis to be performed. Constant strain finite elements are formulated with elastic-viscoplastic constitutive equations. Interfacial debonding is incorporated into the model through interface elements based on the interfacial debonding theory originally presented by Needleman, and modified by Tvergaard. Nonlinear interfacial constitutive equations relate interfacial tractions to displacement discontinuities at the interface. Theoretical predictions are compared with the results of an experimental program conducted on silicon carbide/titanium (SiC/Ti) unidirectional, (O4), and angle-ply, (+34)(sub s), tubular specimens. Multiaxial loading included increments of axial tension, compression, torque, and internal pressure. Loadings were chosen in an effort to distinguish inelastic deformation due to damage from matrix plasticity and separate time-dependent effects from time-independent effects. Results show that fiber/matrix debonding is nonuniform throughout the composite and is a major factor in the effective response. Also, significant creep behavior occurs at relatively low applied stress levels at room temperature. Author (revised)

DYNAMIC BEHAVIOR OF FIBER AND PARTICLE REINFORCED COMPOSITES Final Report
Subhendu K. Datta 12 Mar. 1993 12 p
(Contract N00014-91-J-1297)
(AD-A266905) Avail: CASI HC A03/MF A01

Models were developed for wave propagation in a particle or fiber reinforced composite material in order to describe its dynamic anisotropic and dispersive properties. Model predictions were compared with experimental results for inversion of anisotropic properties of the constituents. Measured properties were related to the microstructure. The effects of interface/interphase on the effective properties were studied by the modeling technique in order to characterize interface/interphase. The characteristics of guided waves in fiber reinforced laminated plates and shells were analyzed to the characterization of anisotropic properties of a lamina. We also investigated the effect of the properties of the interface material layers (bond layers) between the laminae on the dispersion and dynamic response of guided waves. In addition, for thick laminated composites, it is of interest to investigate the dispersion of guided waves in order to model them as homogeneous anisotropic media. The transient response of laminated composite plates due to impact was studied. Of particular interest is the dependence of the response on the duration of impact. The maximum interlaminar stresses for damage development were analyzed. DTIC

CRACK-TIP-OPENING ANGLE MEASUREMENTS AND CRACK TUNNELING UNDER STABLE TEARING IN THIN SHEET 2024-T3 ALUMINUM ALLOY Final Report
D. S. Dawicke and M. A. Sutton (South Carolina Univ., Columbia.) Sep. 1993 33 p
(Contract NAS1-19399; NAG1-1489; RTOP 538-02-10-01)
(NASA-CR-191523; NAS 1.26:191523) Avail: CASI HC A03/MF A01

The stable tearing behavior of thin sheets 2024-T3 aluminum alloy was studied for middle crack tension specimens having initial cracks that were: flat cracks (low fatigue stress) and 45 degrees through-thickness slant cracks (high fatigue stress). The critical crack-tip-opening angle (CTOA) values during stable tearing were measured by two independent methods, optical microscopy and digital image correlation. Results from the two methods agreed well. The CTOA measurements and observations of the fracture surfaces showed that the initial stable tearing behavior of low and high fatigue stress tests is significantly different. The cracks in the low fatigue stress tests underwent a transition from flat-to-slant crack growth, during which the CTOA values were high and significant crack tunneling occurred. After crack growth equal to about the thickness, CTOA reached a constant value of 6 deg and after crack growth equal to about twice the thickness, crack tunneling stabilized. The initial high CTOA values, in the low fatigue crack tests, coincided with large three-dimensional crack front shape changes due to a variation in the through-thickness crack tip constraint. The cracks in the high fatigue stress tests reach the same constant CTOA value after crack growth equal to about the thickness, but produced only a slightly higher CTOA value during initial crack growth. For crack growth on the 45 degree slant, the crack front and local field variables are still highly three-dimensional. However, the constant CTOA values and stable crack front shape may allow the process to be approximated with two-dimensional models. Author (revised)

In this Progress Report, we describe our current research activities concerning the development and implementation of advanced ultrasonic nondestructive evaluation methods applied to the characterization of stitched composite materials and bonded aluminum plate specimens. One purpose of this investigation is to identify and characterize specific features of polar backscatter interrogation which enhance the ability of ultrasound to detect flaws in a stitched composite laminate. Another focus is to explore the feasibility of implementing medical linear array imaging technology as a viable ultrasonic-based nondestructive evaluation method to inspect and characterize bonded aluminum lap joints. As an approach to implementing quantitative ultrasonic inspection methods to both of these materials, we focus on the physics that underlies the detection of flaws in such materials. Properties of fiber reinforced composite materials for aerospatial applications are examined from an economic and technological point of view with focus on automation and flexibility of manufacturing processes. The following topics were included: construction, testing and representation of resins and fibers; construction and calculation; production processes; machine development; component testing and quality assurance; and construction of a computer aided equipment for economic planning and evaluation of production facilities for fiber reinforced composite components. For individual titles, see N94-15255 through N94-15260.

Specific mechanical and chemical properties and material adapted treatments of raw materials for fiber reinforced composites fabrication are investigated. Systematic acquisition and evaluation of data such as modulus of elasticity were performed for each experiment. Surface examinations of glass, carbon and aramid fibers were carried out using electron and infrared spectroscopy, and electron and transmission electron microscopy. A fiber bundle pull-out test was performed for estimation of fiber matrix adhesion. Creep behavior of filaments and laminates from textile glass threads was investigated under constant loading. The influence of cooling velocity on crystallization temperature and enthalpy was characterized in carbon fiber reinforced polyether ether ketone. Thermochemical properties such as failure strength of high temperature thermoplastics and matrix material for fiber reinforced composites were studied. Delaminations with and without cracks, compression damages and failure behavior were observed in several textile reinforced composites with epoxy matrix subjected to tensile stress. ESA

Finite element, transfer, matrix, Fourier series, and finite difference methods are used for optimization of structure of fiber composite reinforced materials. A hybrid process was used with combination of transfer matrix and finite elements methods, for condensation of elastic node structures. The Southwell method, which is based on evaluation of load deformation behavior, was employed for stability studies of composite plates. Transfer matrices were developed for elastic, spatial node, and frame structures using Maxwell-Mohr methods. Delaminations and interlaminar stresses in multilayer composites were calculated for analytic characterization of matrix plastic behavior with consideration of hygrothermal boundary conditions. An articulation was modeled using beam theory for estimation of flexion and shear stresses. A program based on the combination of transfer matrix and finite differences methods was developed for stability, stiffness and strength problems in plates, and allowed the buckling critical load to be determined. Characteristic functions, deduced from short duration tractions tests under temperature and deformation rate variations, were calculated for consideration of temperature and humidity. The hybrid method is found to allow computation time to be significantly reduced. ESA

Processes for development, production, and completion of components, with strong curvature and concave or convex contours, made of fiber reinforced composites with plastic matrix, are described. The focus is on the development of a mathematical model for description of the draping ability of textile surfaces. A multilayer multiaxial stacking of fibers was constructed so that a half finished fabric was obtained in which fiber orientation was fixed by a filament system. A quadratic draping ability tester was designed, in order to obtain a characteristic value for description of fabrics deformation behavior with consideration of roving and filament fineness. Immersion tests were carried out taking into account several laminates stackings and wrapping processes. Draping ability tests were performed with a facility integrated in a computer aided design system. Fiber orientation was defined so that test reproductibility was guaranteed. Draping ability was examined as a function of filament fineness and fabrics construction for a carbon material. It is concluded that fiber reinforced composites have a great usability potential despite their high production costs. ESA

A wrapping process with the perspective of an automated production and tape layering process is developed for manufacturing long fiber reinforced components whose contours have spherical curvature. A production facility was built. The facility was based on a portal robot particularly adapted to fabrication process integration because of its motions and measurement capabilities. It is noticed that wrapping process must be carefully implemented in order to avoid fiber damaging (spool departure and roll up on the wrapping core); eletromagnetic and capacitive sensors must be installed for short term recognition of perturbations such as fiber friction and failure and a strongly oscillating thread tension on a roving spool. The following studies are identified as necessary for tape layering: optimization of the tape layering head and transposition of properties of duroplastic prepreg systems, such as bonding mechanisms; and fiber orientation and viscosity influence, into practical treatment technologies. For heating of thermoplastic rovings, Nd:YAG laser was chosen because its wavelength allows the ray to be coupled in a fiber; alternative processes were examined, such as hot air heating of glass fiber/polyproyle and infrared and CO2 laser heating of carbon fiber/polyether ether ketone system. Avail: CASI HC A03/MF A03

A quality assurance system based on results of nondestructive tests, damage studies, and stiffness calculations is developed for fiber reinforced composites. All available material inspection processes were systematically compiled and analyzed in terms of computer integration, automation possibilities, and integrability in the production course. Detection capabilities of ultrasonic and X-ray inspection were qualitatively and quantitatively compared for flaw and delamination examination. Ultrasonic technology was studied in terms of frequency behavior and acoustic field, evaluating the reflected echo of the sound pulse at a glass plate with a frequency analyzer. Flaw recognition capabilities of holographic interferometry were investigated under thermal loading and internal failures were detected at material surface. Adhesion monitoring in autoclave was performed by dielectrometry; it is shown that electric conductivity increases with temperature and the process, combined with one line control of adhesion, is adequate for bonding cycle optimization. Impact behavior of sandwich structures was examined in order to understand damage initiation in fiber reinforced composites. A quality data base, which provides requirements of computer aided quality assurance and fiber technology, was developed. It is concluded that ultrasonic evaluation has the best potential for automation. ESA

(NASA-CR-194494; NAS 1.26:194494) Avail: CASI HC A03/MF A01

Significant progress has been made on the preparation of carbon fiber composites using advanced polymer resins during the past three months. Current and ongoing research activities reported herein include: (1) Prepregger Hot Sled Operation; (2) Ribbonizing Powder-Impregnated Towpreg; (3) Textile Composites from Powder-Coated Towpreg: Role of Bulk Factor; and (4) Powder Curtain Prepreg Process. During the coming months research will be directed toward further development of the new powder curtain prepregging method and on ways to customize dry powder towpreg for textile and robotic applications in aircraft part fabrication. Studies of multi-tow powder prepregging and ribbon preparation will be conducted in conjunction with continued development of prepegging technology and the various aspects of composite part fabrication using customized towpreg. Also, work will continue on the analysis of the new solution prepegger. For individual titles, see N94-15276 through N94-15277.

Johnston *In* Old Dominion Univ., Polymer Infiltration Studies Jun. 1993 8 p Reprinted from 38th International SAMPE Symposium, 1993 p 1-15 Symposium held 10-13 May 1993 (For primary document see N94-15275 03-24)
Avail: CASI HC A02/MF A01

A multi-purpose prepregging machine has been designed and built for NASA Langley Research Center. The machine has numerous advantages over existing units due to its various modular components. Each of these can be used individually or simultaneously depending on the required prepregging method. A reverse roll coater provides the ability to prepare thin films from typical hot-melt thermoset formulations. Also, if necessary, the design allows direct fiber impregnation within the reverse roll coater gap. Included in the impregnation module is a solution dip tank allowing the fabrication of thermoplastic prepregs from solution. The proceeding modules within the unit consist of four nip stations, two hot-plates, a hot-sled option and a high temperature oven. This paper describes the

advantages of such a modular construction and discusses the various processing combinations available to the prepregger. A variety of high performance prepreg material systems were produced on IM7 (Hercules) carbon fiber. These included LaRC RP46, a PMR-type resin processed from methanol and two polyamide acids, LaRC IA and LaRC ITPI, prpregged from N-methyl pyrrolidinone (NMP). Parameters involved in the production of these prepreg materials are presented as are the mechanical properties of the resulting good quality laminates. A brief introduction into the existing prepregging science is presented. Topics relating to solution prepregging are identified with a focus on the current research effort and its future development. Avail: CASI HC A03/MF A01

Composite manufacturing using the current prepregging technology of impregnating liquid resin into three-dimensionally reinforced textile preforms can be a costly and difficult operation. Alternatively, using polymer in the solid form, grinding it into a powder, and then depositing it onto a carbon fiber tow prior to making a textile preform is a viable method for the production of complex textile shapes. The powder-coated towpreg yarn is stable, needs no refrigeration, contains no solvents and is easy to process into various woven and braided preforms for later consolidation into composite structures. NASA's Advanced Composites Technology (ACT) program has provided an avenue for developing the technology by which advanced resins and their powder-coated preforms may be used in aircraft structures. Two-dimensional braiding and weaving studies using powder-coated towpreg have been conducted to determine the effect of resin content, towpreg size and twist on textile composite properties. Studies have been made to customize the towpreg to reduce friction and bulk factor. Processing parameters have been determined for three epoxy resin systems on eight-harness satin fabric, and on more advanced 3-D preform architectures for the downselected resin system. Processing effects and the resultant mechanical properties of these textile composites will be presented and compared. Author

(DE93-015155; ANL/MCT/CP-78063; CONF-930438-21) Avail: CASI HC A03/MF A01

Phosphate-bonded cements have been proposed as candidates for solidification and stabilization of mixed wastes. Magnesium ammonium phosphate (MAP) has been investigated as a candidate material. Detailed physical and mechanical properties of MAP cement are reported. It is synthesized by the route of reaction of calcined MgO and ammonium phosphate solution. Samples are made by setting the cement at room temperature and slight pressure. The porosity is reduced to approximately 11% by impregnation of ammonium phosphate solution. Detailed mechanical properties such as flexural strength, fracture toughness, and compression strength are reported and fracture mechanical analyses supported with scanning electron microscopy are provided. Properties of composites of these cements with zeolites, which may be used for containment of radioactive as well as chemical waste are studied. We demonstrate that the strengths of these composites compare well with portland cement even after 50% loading of zeolites. Fracture mechanical implications of such loadings are given. DOE

ANISOTROPIC DAMAGE MECHANICS MODELING IN METAL MATRIX COMPOSITES Final Report, 1 Apr. 1992 - 31 Mar. 1993
George Z. Voyiadjis, Peter I. Kattan, Anthony R. Venson, and Taehyo Park 15 May 1993 142 p
(Grant AF-AFOSR-0227-90)
(AD-A266328; AFOSR-93-0431TR) Avail: CASI HC A07/MF A02

A consistent and systematic theory is developed for the analysis of damage mechanisms in metal matrix composites (MMC's). The theory involves both analytical and experimental procedures for the quantification of certain types of damage in MMC's. The analytical model involves both overall and local approaches to characterize damage in these materials. A series of experiments are conducted for micro- and macro-structural

characterization of the MMC. Experiments were conducted on a titanium aluminide SiC-reinforced metal matrix composite. Center-cracked plates with laminate layups of (0/90)s, and (+/-45)s were tested under uniaxial tension. In order to investigate and model damage evolution, each of the specimens is loaded to different load levels ranging from fracture load down to 70% of the fracture load. Scanning electron microscopy (SEM) is performed on representative cross-sections of the damaged specimens. The measured crack densities are then used to define the damage parameters that are used in the theoretical model. DTIC

EVALUATION OF THE INTERFACIAL MECHANICAL PROPERTIES IN FIBER-REINFORCED CERAMIC COMPOSITES
M. K. Ferber, A. A. Wereszczak, L. Riester, R. A. Lowden, and K. K. Chawla (New Mexico Inst. of Mining and Technology, Socorro.) 1993 40 p Presented at the 17th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 11-15 Jan. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015494; CONF-930164-10) Avail: CASI HC A03/MF A01

The application of a micro-indentation technique to the measurement of interfacial properties in fiber reinforced ceramic composites is examined. Specific fiber/matrix systems included SiC/glass, SiC/macro-defect-free (MDF) cement, SiC/SiC, and mullite/glass. The effect of fiber coatings upon the interfacial properties was also investigated. These properties which included the debond strength, interfacial shear stress, and residual axial fiber stress were evaluated by measuring the force-displacement curves generated during load-unload cycles. Estimates of these three stress values were obtained by matching the experimental force-displacement curves with data predicted from an existing model. In general the SiC/glass composites exhibited the lowest values of the interfacial shear and debond stresses. The sliding characteristics of the SiC/MDF cement and SiC/SiC composites were strongly influenced by the residual axial stress and the nature of the fiber coating. In the case of the mullite/glass composite, the high values of the interfacial shear and debond stresses reduced the measurement sensitivity, thereby increasing the uncertainty in the estimates of the interfacial properties. ELECTROSTATIC FIBER SPREADER INCLUDING A CORONA DISCHARGE DEVICE Patent
Jonathan M. Peritt, inventor (to Navy), Richard Everett, inventor (to Navy), and Alan Edelstein, inventor (to Navy) 6 Apr. 1993 6 p Filed 5 Nov. 1991
(AD-D015793; US-Patent-5,200,620; US-Patent-Appl-SN-788018; US-Patent-Class-250-324) Avail: US Patent and Trademark Office

A fiber spreader is provided which reduces fiber damage that occurs during spreading. The fiber spreader includes a thin electrically grounded support sheet for supporting a layer of fibers on one surface thereof. The fibers supported on the support sheet are guided by a plurality of guide rollers past at least one corona discharge region at which the fibers are spread substantially uniformly. A motor driven spool advances the support sheet past the corona discharge region. The fibers are attached to the support sheet by an electrostatic attraction. The guide rollers are positioned so as to provide at least one region in which the sheet and the fibers are physically separated to allow for the uniform spreading of the fibers. After the fibers are spread, the fibers and the support sheet are united again and collected on a motor-driven spool. DTIC

CONTINUOUS FABRICATION OF SiC FIBER TOWS BY CHEMICAL VAPOR DEPOSITION Final Report, 1 Sep. 1991 - 31 Dec. 1992
W. J. Lackey, J. A. Hanigofsky, G. B. Freeman, R. D. Hardin, and B. N. Beckloff 1 Jan. 1993 106 p
(AD-A266460; GIT-A-9056; WL-TR-93-4013) Avail: CASI HC A06/MF A02

The objective of this 15-month effort was to determine the feasibility of preparing small diameter SiC fiber tows by chemical vapor deposition for use as reinforcing fibers in ceramic and metal matrix composites. The proposed goal of codepositing SiC + Si3N4 was modified 2 months into the project in order to concentrate on fiber coating technology for SiC fiber development only. Our approach was to develop spreading techniques for filaments of the substrate tow so that SiC could be rapidly deposited without bonding the filaments together. Following some initial experiments, a statistical processing study was completed to define processing conditions where the desired 5 micrometers SiC coating thickness would be achieved. Processing-property correlations were determined using multiple regression analysis. Stress calculations were used to aide in substrate selection--the carbon fiber which had the minimal fiber/coating stress due to thermal expansion mismatch was determined to be the Amoco T-300, unsized, and untwisted fiber. Several fiber spreading techniques were evaluated to minimize fiber agglomeration. Cyclic tension, in conjunction with gas jets or stationary and moving rollers was determined to be ineffective for spreading the fiber tow. The most promising results, however, were obtained from electromagnetic spreading of the fiber tow. DTIC

STRESS ANALYSIS OF LAMINATED COMPOSITES WITH PREFORMED HOLES. PART 1: SINGLE PLIES WITH EMBEDDED MATERIAL DISCONTINUITIES Final Report, 26 May - 30 Sep. 1992
Endel V. Iarve 30 Sep. 1992 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-89-C-5609)
(AD-A266524; WL-TR-93-4063-Pt-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An analytical and experimental study was conducted to develop a computational model adequate for stress analyses of AS4/3501-6 composite plates containing preformed 1/4 diameter holes, which were found in previous and parallel experimental studies to possess superior open-hole tension and compression strengths relative to composites with drilled holes of equal diameter. The preformed-hole composites contain embedded material discontinuities resulting from the interpenetration of adjacent composite layers in the actual, laminated systems. The effort reported addresses the initial development of the model for single layers containing the material discontinuities present in laminates. The analytical method is suitable for adaptation to problems involving smart materials, electronic packaging, micro-electromechanical systems, and joining/fastening. The proposed computational model is based on spline approximations of the displacement components. Solutions were obtained relative to curvilinear coordinates that mapped the preformed hole region onto a rectangular region and the embedded material boundaries into coordinate lines. DTIC

EFFECT OF IMPACT DAMAGE AND OPEN HOLE ON COMPRESSIVE STRENGTH OF HYBRID COMPOSITE LAMINATES Final Report, 1 Jun. 1992 - 31 May 1993
Clement Hiel (National Aeronautics and Space Administration. Ames Research Center, Moffett Field, CA.) and H. F. Brinson 31 May 1993 77 p
(Contract NCC2-724)
(NASA-CR-194603; NAS 1.26:194603) Avail: CASI HC A05/MF A01

Impact damage tolerance is a frequently listed design requirement for composites hardware. The effect of impact damage and open hole size on laminate compressive strength was studied on sandwich beam specimens which combine CFRP-GFRP hybrid skins and a syntactic foam core. Three test specimen configurations have been investigated for this study. The first two were sandwich beams which were loaded in pure bending (by four point flexure). One series had a skin damaged by impact, and the second series had a circular hole machined through one of the skins. The reduction of compressive strength with increasing damage (hole) size was compared. Additionally a third series of uniaxially loaded open hole compression coupons were tested to generate baseline data for comparison with both series of sandwich beams. For individual titles, see N94-16837 through N94-16837.

LOW AND HIGH VELOCITY IMPACT RESPONSE OF THICK HYBRID COMPOSITES
Clement Hiel and Ori Ishai *In* Texas Univ., Effect of Impact Damage and Open Hole on Compressive Strength of Hybrid Composite Laminates 31 May 1993 p 1149-1159 (For primary document see N94-16836 03-24)
Avail: CASI HC A03/MF A01

The effects of low and high velocity impact on thick hybrid composites (THC's) were experimentally compared. Test Beams consisted of CFRP skins which were bonded onto an interleaved syntactic foam core and cured at 177 C (350 F). The impactor tip for both cases was a 16 mm (0.625 inch) steel hemisphere. In spite of the order of magnitude difference in velocity ranges and impactor weights, similar relationships between impact energy, damage size, and residual strength were found. The dependence of the skin compressive strength on damage size agree well with analytical open hole models for composite laminates and may enable the prediction of ultimate performance for the damaged composite, based on visual inspection. The FIBER-TEX 1992 proceedings contain the papers presented at the conference held on 27-29 Oct. 1992 at Drexel University. The conference was held to create a forum to encourage an interrelationship of the various disciplines involved in the fabrication of materials, the types of equipment, and the processes used in the production of advanced composite structures. Topics discussed were advanced engineering fibers, textile processes and structures, structural fabric production, mechanics and characteristics of woven composites, and the latest requirements for the use of textiles in

the production of composite materials and structures as related to global activities focused on textile structural composites. For individual titles, see N94-16846 through N94-16865.

AN OVERVIEW OF THE NASA TEXTILE COMPOSITES PROGRAM

H. Benson Dexter *In its* FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 1-31 (For primary document see N94-16845 03-24)

Avail: CASI HC A03/MF A03

The NASA Langley Research Center is conducting and sponsoring research to explore the benefits of textile reinforced composites for civil transport aircraft primary structures. The objective of this program is to develop and demonstrate the potential of affordable textile reinforced composite materials to meet design properties and damage tolerance requirements of advanced aircraft structures. In addition to in-house research, the program includes major participation by the aircraft industry and aerospace textile companies. The major program elements include development of textile preforms, processing science, mechanics of materials, experimental characterization of materials, and development and evaluation of textile reinforced composite structural elements and subcomponents. The NASA Langley in-house research is focused on science-based understanding of resin transfer molding (RTM), development of powder-coated towpreg processes, analysis methodology, and development of a performance database on textile reinforced composites. The focus of the textile industry participation is on development of multidirectional, damage-tolerant preforms, and the aircraft industry participation is in the areas of innovative design concepts, cost-effective fabrication, and testing of textile reinforced composite structural elements and subcomponents. Textile processes such as 3-D weaving, 2-D and 3-D braiding, and knitting/stitching are being compared with conventional laminated tape processes for improved damage tolerance. Through-the-thickness reinforcements offer significant damage tolerance improvements. However, these gains must be weighed against potential loss in in-plane properties such as strength and stiffness. Analytical trade studies are underway to establish design guidelines for the application of textile material forms to meet specific loading requirements. Fabrication and testing of large structural components are required to establish the full potential of textile reinforced composite materials. The goals of the NASA Langley-sponsored research program are to demonstrate technology readiness with subscale composite components by 1995 and to verify the performance of full-scale composite primary aircraft structural components by 1997. The status of textile reinforced composite structural elements under development by Boeing, Douglas, Lockheed, and Grumman are presented. Included are braided frames and woven/stitched wing and fuselage panels. Author

TECHNO-ECONOMIC REQUIREMENTS FOR AUTOMOTIVE COMPOSITES

Scot Arnold *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 33-48 (For primary document see N94-16845 03-24)

Avail: CASI HC A03/MF A03

New technology generally serves two main goals of the automotive industry: one is to enable vehicles to comply with various governmental regulations and the other is to provide a competitive edge in the market. The latter goal can either be served through improved manufacturing and design capabilities, such as computer aided design and computer aided manufacturing, or through improved product performance, such as anti-lock braking (ABS). Although safety features are sometimes customer driven, such as the increasing use of airbags and ABS, most are determined by regulations as outlined by the Federal Motor Vehicle Safety Standards (FMVSS). Other standards, set by the Environmental Protection Agency, determine acceptable levels of emissions and fuel consumption. State governments, such as in California, are also setting precedent standards, such as requiring manufacturers to offer zero-emission vehicles as a certain fraction of their sales in the state. The drive to apply new materials in the automobile stems from the need to reduce weight and improve fuel efficiency. Topics discussed include: new lightweight materials; types of automotive materials; automotive composite applications; the role for composite materials in automotive applications; advantages and disadvantages of composite materials; material substitution economics; economic perspective; production economics; and composite materials production economics.

DESIGN AND COST DRIVERS IN 2-D BRAIDING

Alberto Morales *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 69-77 (For primary document see N94-16845 03-24)

Avail: CASI HC A02/MF A03

Fundamentally, the braiding process is a highly efficient, low cost method for combining single yarns into circumferential shapes, as evidenced by the number of applications for continuous sleeving. However, this braiding approach cannot fully demonstrate that it can drastically reduce the cost of complex shape structural preforms. Factors such as part geometry, machine design and configuration, materials used, and operating parameters are described as key cost drivers and what is needed to minimize their effect on elevating the cost of structural braided preforms.

WEAVING MULTI-LAYER FABRICS FOR REINFORCEMENT OF ENGINEERING COMPONENTS

B. J. Hill, R. McIlhagger, and P. McLaughlin *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 79-96 (For primary document see N94-16845 03-24)

Avail: CASI HC A03/MF A03

The performance of interlinked, multi-layer fabrics and near net shape preforms for engineering applications, woven on a 48 shaft dobby loom using glass, aramid, and carbon continuous filament yarns is assessed. The interlinking was formed using the warp yarns. Two basic types of structure were used. The first used a single warp beam and hence each of the warp yarns followed a similar path to form four layer interlinked reinforcements and preforms. In the second two warp beams were used, one for the interlinking yarns which pass from the top to the bottom layer through-the-thickness of the fabric and vice versa, and the other to provide 'straight' yarns in the body of the structure to carry the axial loading. Fabrics up to 15mm in thickness were constructed with varying amounts of through-the-thickness reinforcement. Tapered T and I sections were also woven, with the shaping produced by progressive removal of ends during construction. These fabrics and preforms were impregnated with resin and cured to form composite samples for testing. Using these two basic types of construction, the influence of reinforcement construction and the proportion and type of interlinking yarn on the performance of the composite was assessed. EFFECT OF TOW ALIGNMENT ON THE MECHANICAL PERFORMANCE OF 3D WOVEN TEXTILE COMPOSITES

Timothy L. Norman, Patti Allison (General Electric Co., Cincinnati, OH.), Jack W. Baldwin (General Electric Co., Cincinnati, OH.), Brian K. Gracias (General Electric Co., Cincinnati, OH.), and Dave Seesdorf (Westinghouse

Electric Corp., Pittsburgh, PA.) *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 97-113 Sponsored by GE (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

Three-dimensional (3D) woven preforms are currently being considered for use as primary structural components. Lack of technology to properly manufacture, characterize and predict mechanical properties, and predict damage mechanisms leading to failure are problems facing designers of textile composite materials. Two material systems with identical specifications but different manufacturing approaches are investigated. One manufacturing approach resulted in an irregular (nonuniform) preform geometry. The other approach yielded the expected preform geometry (uniform). The objectives are to compare the mechanical properties of the uniform and nonuniform angle interlock 3D weave constructions. The effect of adding layers of laminated tape to the outer surfaces of the textile preform is also examined. Damage mechanisms are investigated and test methods are evaluated.

The development of modern technologies demands the creation of new nonmetallic, fibrous materials with specific properties. The fibers and materials developed by NII 'Chimvolokno', St. Petersburg, can be divided into two groups. The first group includes heat-resistant fibers, fire-resistant fibers, thermotropic fibers, fibers for medical application, and textile structures. The second group contains refractory fibers, chemoresistant and antifriction fibers, fibers on the basis of polyvinyl alcohol, microfiltering films, and paperlike and nonwoven materials. In cooperation with NPO 'Chimvolokno' MYTITSHI, we developed and started producing heat-resistant high-strength fibers on the base of polyhetarearilin and aromatic polyimides (SVM and terlon); heat-resistant fibers on the base of polyemede (aramid); fire-retardant fibers (togilen); chemoresistant and antifriction fibers on the basis of homo and copolymers of polytetrafluoroethylene (polyfen and ftorin); and water soluble, acetylated, and high-modulus fibers from polyvinyl alcohol (vylen). Separate reports will deal with textile structures and thermotropic fibers, as well as with medical fibers. One of the groups of refractory fibers carbon fibers (CF) and the corresponding paperlike nonwoven materials are discussed in detail. Also, composite materials (CM) and their base, which is the subject of the author's research since 1968, is discussed.

Efferent sorption methods of organism detoxication (by medical trend) are presented. Recently, specialists have shown their keen interest in the problem of treating exogenous and endogenous intoxications. This was stipulated by the growing production and accumulation of chemical products for industrial, agricultural, and domestic needs. To solve this problem the industrial production of carbon fibrous adsorbents was developed and implemented at NII Chimvolokno in St. Petersburg. A description of the carbon fibers is given. Also, application of modern composite materials for manufacturing compression-distraction apparatus used for setting fractured bones is described. Derived from text

INFLUENCE OF FIBER PACKING STRUCTURE ON PERMEABILITY
Zhong Cai and Alexander L. Berdichevsky (CR Industries, Elgin, IL.) *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 167-181 (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

The study on the permeability of an aligned fiber bundle is the key building block in modeling the permeability of advanced woven and braided preforms. Available results on the permeability of fiber bundles in the literature show that a substantial difference exists between numerical and analytical calculations on idealized fiber packing structures, such as square and hexagonal packing, and experimental measurements on practical fiber bundles. The present study focuses on the variation of the permeability of a fiber bundle under practical process conditions. Fiber bundles are considered as containing openings and fiber clusters within the bundle. Numerical simulations on the influence of various openings on the permeability were conducted. Idealized packing structures are used, but with introduced openings distributed in different patterns. Both longitudinal and transverse flow are considered. The results show that openings within the fiber bundle have substantial effect on the permeability. In the longitudinal flow case, the openings become the dominant flow path. In the transverse flow case, the fiber clusters reduce the gap sizes among fibers. Therefore

the permeability is greatly influenced by these openings and clusters, respectively. In addition to the porosity or fiber volume fraction, which is commonly used in the permeability expression, another fiber bundle status parameter, the ultimate fiber volume fraction, is introduced to capture the disturbance within a fiber bundle. CHARACTERIZATION OF VOIDS FORMED DURING LIQUID IMPREGNATION OF NONWOVEN MULTIFILAMENT GLASS NETWORKS AS RELATED TO COMPOSITE PROCESSING
Anant D. Mahale, Robert K. Prudhomme, and Ludwig Rebenfeld *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 183-202 Prepared in cooperation with Princeton Univ., NJ (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

A technique based on matching the refractive index of an invading liquid to that of a fiber mat was used to study entrapment of air ('voids') that occurs during forced in-plane radial flow into nonwoven multifilament glass networks. The usefulness of this technique is demonstrated in quantifying and mapping the air pockets. Experiments with a series of fluids with surface tensions varying from 28 x 10(exp -3) to 36 x 10(exp -3) N/m, viscosities from 45 x 10(exp -3) to 290 x 10(exp -3) Pa.s, and inlet flow rates from 0.15 x 10(exp -6) to 0.75 x 10(exp -6) m(exp 3)/s, showed that void content is a function of the capillary number characterizing the flow process. A critical value of capillary number, Ca = 2.5 x 10(exp -3), identifies a zone below which void content increases exponentially with decreasing capillary number. Above this critical value, negligible entrapment of voids is observed. Similar experiments carried out on surface treated nonwoven mats spanning a range of equilibrium contact angles from 20 deg to 78 deg showed that there is a critical contact angle above which negligible entrapment is observed. Below this value, there is no apparent effect of contact angle on the void fraction - capillary number relationship described earlier. Studies on the effect of filament wettability, and fluid velocity and viscosity on the size of the entrapment (voids) were also carried out. These indicate that larger sized entrapments which envelop more than one pore are favored by a low capillary number in comparison to smaller, pore level bubbles. Experiments were carried out on deformed mats - imposing high permeability spots at regular intervals on a background of low permeability. The effect of these spatial fluctuations in heterogeneity of the mat on entrapment is currently being studied. Author (revised)

DEVELOPMENT OF BRAIDED FIBER SEALS FOR ENGINE APPLICATIONS
Zhong Cai (Drexel Univ., Philadelphia, PA.), Rajakkannu Mutharasan (Drexel Univ., Philadelphia, PA.), Frank K. Ko (Drexel Univ., Philadelphia, PA.), Guang-Wu Du (Drexel Univ., Philadelphia, PA.), and Bruce M. Steinetz *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 203-214 (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

A new type of braided fiber seal was developed for high temperature engine applications. Development work performed includes seal design, fabrication, leakage flow testing, and flow resistance modeling. This new type of seal utilizes the high flow resistance of tightly packed fibers and the conformability of textile structures. The seal contains a core part with aligned fibers, and a sheath with braided fiber layers. Seal samples are made by using the conventional braiding process. Leakage flow measurements are then performed. Mass flow rate versus the simulated engine pressure and preload pressure is recorded. The flow resistance of the seal is analyzed using the Ergun equation for flow through porous media, including both laminar and turbulent effects. The two constants in the Ergun equation are evaluated for the seal structures. Leakage flow of the seal under the test condition is found to be in the transition flow region. The analysis is used to predict the leakage flow performance of the seal with the determined design parameters. Author (revised)

QUANTIFICATION OF PROCESSING ARTIFACTS IN TEXTILE COMPOSITES
Christopher M. Pastore *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 215-234 Sponsored in part by North Carolina Supercomputing Association (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

One of the greatest difficulties in developing detailed models of the mechanical response of textile reinforced composites is an accurate model of the reinforcing elements. In the case of elastic property prediction, the variation of fiber position may not have a critical role in performance. However, when considering highly localized stress events, such as those associated with cracks and holes, the exact position of the reinforcement probably dominates the failure mode. Models were developed for idealized reinforcements which provide an insight into the local behavior. However, even casual observations of micrographical images reveals that the actual material deviates strongly from the idealized models. Some of the deviations and causes are presented for triaxially braided and three dimensionally woven textile composites. The necessary modeling steps to accommodate these variations are presented with some examples. Some of the ramifications of not accounting for these discrepencies are also addressed. STOCHASTIC DAMAGE EVOLUTION IN TEXTILE LAMINATES
Yuris A. Dzenis, Alexander E. Bogdanovich (North Carolina State Univ., Raleigh.), and Christopher M. Pastore (North Carolina State Univ., Raleigh.) *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 235-248 (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

A probabilistic model utilizing random material characteristics to predict damage evolution in textile laminates is presented. Model is based on a division of each ply into two sublaminas consisting of cells. The probability of cell failure is calculated using stochastic function theory and maximal strain failure criterion. Three modes of failure, i.e. fiber breakage, matrix failure in transverse direction, as well as matrix or interface shear cracking, are taken into account. Computed failure probabilities are utilized in reducing cell stiffness based on the mesovolume concept. A numerical algorithm is developed predicting the damage evolution and deformation history of textile laminates. Effect of scatter of fiber orientation on cell properties is discussed. Weave influence on damage accumulation is illustrated with the help of an example of a Kevlar/epoxy laminate. Author (revised)

DEVELOPMENT OF TEST METHODS FOR TEXTILE COMPOSITES
John E. Masters, Peter G. Ifju (Virginia Polytechnic Inst., Blacksburg.), and Mark J. Fedro (Boeing Defense and Space Group, Philadelphia, PA.) *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 249-269 (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

NASA's Advanced Composite Technology (ACT) Program was initiated in 1990 with the purpose of developing less costly composite aircraft structures. A number of innovative materials and processes were evaluated as a part of this effort. Chief among them are composite materials reinforced with textile preforms. These new forms of composite materials bring with them potential testing problems. Methods currently in practice were developed over the years for composite materials made from prepreg tape or simple 2-D woven fabrics. A wide variety of 2-D and 3-D braided, woven, stitched, and knit preforms were suggested for application in the ACT program. The applicability of existing test methods to the wide range of emerging materials bears investigation. The overriding concern is that the values measured are accurate representations of the true material response. The ultimate objective of this work is to establish a set of test methods to evaluate the textile composites developed for the ACT Program. Author (revised)

THREE-DIMENSIONAL ANALYSIS OF ANISOTROPIC SPATIALLY REINFORCED STRUCTURES
Alexander E. Bogdanovich (Latvian P. Stuchka State Univ., Riga.) *In*

NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 271-304 (For primary document see N94-16845 03-24)
Avail: CASI HC A03/MF A03

The material-adaptive three-dimensional analysis of inhomogeneous structures based on the meso-volume concept and application of deficient spline functions for displacement approximations is proposed. The general methodology is demonstrated on the example of a brick-type mosaic parallelepiped arbitrarily composed of anisotropic meso-volumes. A partition of each meso-volume into sub-elements, application of deficient spline functions for a local approximation of displacements and, finally, the use of the variational principle allows one to obtain displacements, strains, and stresses at anypoint within the structural part. All of the necessary external and internal boundary conditions (including the conditions of continuity of transverse stresses at interfaces between adjacent meso-volumes) can be satisfied with requisite accuracy by increasing the density of the sub-element mesh. The application of the methodology to textile composite materials is described. Several numerical examples for woven and braided rectangular composite plates and stiffened panels under transverse bending are considered. Some typical effects of stress concentrations due to the material inhomogeneities are demonstrated. Author (revised)

TECHNO-ECONOMIC REQUIREMENTS FOR COMPOSITE AIRCRAFT COMPONENTS
Ray Palmer *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 305-341 (For primary document see N94-16845 03-24)
(Contract NAS1-18862)
Avail: CASI HC A03/MF A03

The primary reason for use of composites is to save structural weight. A well designed composite aircraft structure will usually save 25-30 percent of a well designed metal structure. The weight savings then translates into improved performance of the aircraft in measures of greater payload, increased flying range or improved efficiency - less use of fuel. Composite materials offer technical advantages. Key technical advantages that composites offer are high stiffness, tailored strength capability, fatigue resistance, and corrosion resistance. Low thermal expansion properties produce dimensionally stable structures over a wide range of temperature. Specialty resin 'char' forming characteristics in a fire environment offer potential fire barrier application and safer aircraft. The materials and processes of composite fabrication offer the potential for lower cost structures in the near future. The application of composite materials to aircraft are discussed. AEROELASTIC AIRFOIL SMART SPAR **c05**
Skott Greenhalgh, Christopher M. Pastore, and Moishe Garfinkle (Drexel Univ., Philadelphia, PA.) *In* NASA. Langley Research Center, FIBER-TEX 1992: The Sixth Conference on Advanced Engineering Fibers and Textile Structures for Composites Aug. 1993 p 343-351 (For primary document see N94-16845 03-24)
Avail: CASI HC A02/MF A03

Aircraft wings and rotor-blades are subject to undesirable bending and twisting excursions that arise from unsteady aerodynamic forces during high speed flight, abrupt maneuvers, or hard landings. These bending excursions can range in amplitude from wing-tip flutter to failure. A continuous-filament construction 'smart' laminated composite box-beam spar is described which corrects itself when subject to undesirable bending excursions or flutter. The load-bearing spar is constructed so that any tendency for the wing or rotor-blade to bend from its normal position is met by opposite twisting of the spar to restore the wing to its normal position. Experimental and theoretical characterization of these spars was made to evaluate the torsion-flexure coupling associated with symmetric lay-ups. The materials used were uniweave AS-4 graphite and a matrix comprised of Shell 8132 resin and U-40 hardener. Experimental tests were conducted on five spars to determine spar twist and bend as a function of load for 0, 17, 30, 45 and 60 deg fiber angle lay-ups. Symmetric fiber lay-ups do exhibit torsion-flexure couplings. Predictions of the twist and bend versus load were made for different fiber orientations in laminated spars using a spline function structural analysis. The analytical results were compared with experimental results for validation. Excellent correlation between experimental and analytical values was found. Author (revised)

FIBER STRENGTH UTILIZATION IN CARBON/CARBON COMPOSITES Technical Report
R. J. Zaldivar, Gerry S. Rellick, and J. M. Yang 15 May 1993 34 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-88-C-0089)
(AD-A267713; TR-92(2935)-1; SMC-TR-93-33) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The utilization of tensile strength of carbon fibers in unidirectional carbon/carbon (C/C) composites was studied for a series of four mesophase-pitch-based carbon fibers in a carbon matrix derived from a polyarylacetylene (PAA) resin. The fibers had moduli of 35, 75, and 130 Mpsi. Composite processing conditions ranged from the cured-resin state to various heat-treatment temperatures (HTTs) from 1100 to 1750 deg C for the C/Cs. Room-temperature tensile strength and modulus were

measured for the various processing conditions, and were correlated with SEM observations of fracture surfaces, fiber and matrix microstructures, and fiber/matrix interphase structures. Fiber tensile strength utilization (FSU) is defined as the ratio of apparent fiber strength in the C/C to the fiber strength in an epoxy-resin-matrix composite. Carbonization heat treatment to 1100 deg C results in a battle carbon matrix that bonds strongly with the three lower modulus fibers, resulting in matrix-dominated failure at FSU values of 24 to 35%. However, the composite with the 130-Mpsi modulus filament had an FSU of 79%. It is attributed to a combination of tough fracture within the filament itself and a weaker fiber/matrix interface. Both factors lead to crack deflection and blunting rather than to crack propagation. The presence of a weakened interface is inferred from observations of fiber pullout. Much of the FSU of the three lower modulus fibers is recovered by HIT to 2100 or 2400 deg C, principally as a result of interface weakening, which works to prevent matrix-dominated fracture. With HTT to 2750 deg C, there is a drop in FSU for all the composites; it is apparently the result of a combination of fiber degradation and reduced matrix stress-transfer capability. DTIC

PREDICTION OF THERMAL CYCLING INDUCED CRACKING IN POLYMER MATRIX COMPOSITES Semiannual Report, Feb. - Jul. 1993

Hugh L. McManus Nov. 1993 36 p

(Grant NAG1-1493)

(NASA-CR-194677; NAS 1.26:194677) Avail: CASI HC A03/MF A01

This report summarizes the work done in the period February 1993 through July 1993 on the 'Prediction of Thermal Cycling Induced Cracking In Polymer Matrix Composites' program. An oral presentation of this work was given to Langley personnel in September of 1993. This document was prepared for archival purposes. Progress studies have been performed on the effects of spatial variations in material strength. Qualitative agreement was found with observed patterns of crack distribution. These results were presented to NASA Langley personnel in November 1992. The analytical methodology developed by Prof. McManus in the summer of 1992 (under an ASEE fellowship) has been generalized. A method for predicting matrix cracking due to decreasing temperatures and/or thermal cycling in all plies of an arbitrary laminate has been implemented as a computer code. The code also predicts changes in properties due to the cracking. Experimental progressive cracking studies on a variety of laminates were carried out at Langley Research Center. Results were correlated to predictions using the new methods. Results were initially mixed. This motivated an exploration of the configuration of cracks within laminates. A crack configuration study was carried out by cutting and/or sanding specimens in order to examine the distribution of cracks within the specimens. These investigations were supplemented by dye-penetrant enhanced X-ray photographs. The behavior of thin plies was found to be different from the behavior of thicker plies (or ply groups) on which existing theories are based. Significant edge effects were also noted, which caused the traditional metric of microcracking (count of cracks on a polished edge) to be very inaccurate in some cases. With edge and configuration taken into account, rough agreement with predictions was achieved. All results to date were reviewed with NASA Langley personnel in September 1993. Derived from text

ASPECTS OF HIGH TEMPERATURE DAMAGE IN FIBER REINFORCED TITANIUM METAL MATRIX COMPOSITES Annual Report, Jun. 1992 - Jun. 1993

H. Ghonem, D. Zheng, M. Tamin, Y. Win, and M. Thompson (United Technologies Corp., East Hartford, CT.) Jul. 1993 153 p

(Contract F49620-92-J-0291)

(AD-A267907; URI-MSL-93-10; AFOSR-93-0599TR) Avail: CASI HC A08/MF A02

Aspects associated with high temperature damage in fiber reinforced Metal Matrix Composites (MMC) were investigated and are presented in this report in the form of five separate sections. In the first section, the fatigue and fatigue crack growth characteristics in neat laminates made of Timetal 21S were studied in relation to both temperature and loading frequency effects. The second section deals with the evolution of the thermal residual stresses in the composite when cooling from consolidation temperature or subjecting the composite to then-nal cycles. A new mechanical simulation method capable of measuring the induced residual stress on real; time basis has been developed in this study. The third section extends this issue to the time-dependent internal stress and strain states of MMC's under the thermomechanical loading conditions. Here, a new micromechanical model employing the four-phase concentric cylinder configuration has been proposed. Based on this model, the time-dependent behavior of continuous fiber reinforced metal matrix composites has been evaluated for the SCS-6/Timetal 21S composite. These results are presented in the fourth section. The last section of this report deals with the high temperature fatigue crack growth characteristics of the continuous fiber reinforced titanium metal matrix composite sigma l240/Timetal 12lS. The time-dependent features of the crack growth was examined in relation to the variation of both testing temperature and loading frequency. The principal damage mechanism of this composite under the load condition employed was identified to be the crack bridging and fiber/matrix debonding confined to regions near the crack surfaces. DTIC

DIRECT OBSERVATION OF FRACTURE OF CAS-GLASS/SiC COMPOSITES AND PROCESSING OF TOUGHENED ALUMINA Final Report, 1 Apr. 1991 - 31 Mar. 1992

H. R. Shercliff, G. Vekinis, M. F. Ashby, and P. W. Beaumont Sep. 1992 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant AF-AFOSR-0221-91)

(AD-A268275; CUED/C-MATS/TR203; AFOSR-93-0582TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The first part of the report describes the continuation of a test series which has been undertaken on the laminated CAS-glass SiC fiber reinforced material provided by the USAF Materials Laboratory, Dayton, Ohio. Fracture mechanisms have been studied in four-point bend and in two geometries - double cantilever beam and double edge-notched tension. Dynamic in-situ scanning electron microscopy has enabled a clear characterization of sub-critical damage, and crack interactions prior to final failure, both of which have a strong influence on the material failure strength. The second part of the report describes preliminary studies on the fracture behavior of alumina toughened with ductile metal reinforcements. Specimens of alumina reinforced with discrete particles (mainly cobalt) have been produced by pretreating metal powders and mixing them with alumina powder followed by sintering under protective atmospheres. Processing conditions have been developed, and fracture surfaces studied in the scanning electron microscope. Crack bridging by metal ligaments has been observed. The ligaments fail by necking and/or shearing. The materials and processing route appear to be promising, especially in terms of controlling the interfacial reactions and strength. DTIC

N94-17473 Air Force Inst. of Tech., Wright-Patterson AFB, OH.

EVALUATION OF HYBRID REINFORCEMENT (FIBER-REINFORCED-PLASTIC ROD WITH STEEL CORE) M.S. Thesis

Markus J. Henneke Aug. 1993 175 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A268009; AFIT/CI/CIA-93-114) Avail: CASI HC A08

The corrosion of concrete reinforcement is a problem that seriously affects structures exposed to harsh environments (parking garages, marine structures, chemical plants, etc.). Currently the most popular method of corrosion protection is epoxy-coating for steel rebars and tendons. As an alternative to epoxy-coating, this project presents an initial evaluation of hybrid reinforcement. Hybrid reinforcement consists of a FRP (fiber-reinforced-plastic) skin with a steel core. The FRP skin (fully-bonded) is made of braided, epoxy-impregnated aramid or vinylon fiber. Besides protecting the steel core from corrosion, the FRP skin provides a structural function. Hybrid reinforcement allows specifying a reinforcement behavior by changing the core-to-skin cross-sectional ratios and by combining different core and skin materials. Uniaxial tensile test results are presented to show the characteristics of different hybrid rods. Results from beams reinforced with hybrid rods are presented to demonstrate the flexural behavior of concrete members reinforced with hybrid rods. DTIC

THERMO-MECHANICAL ANALYSIS OF OXIDATION PROTECTED CARBON-CARBON COMPOSITES Annual Report, Feb. 1992 - Feb. 1993

Zvi Hashin, Mark Jones, and Thomas Cassin Jun. 1993 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-C-0024)
(AD-A268191; MSC-TPR-3318/1507; AFOSR-93-0591TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The AFOSR oxidation-protected C-C composite program is focused on developing and verifying mathematical models predicting the thermomechanical properties of exposed carbon-carbon composites. These models will be utilized to make judgements on the merits of both current and future materials concepts for oxidation resistance. These efforts are focused on the understanding of the formation and growth of damage within these materials and on the influence of oxidation protection constituents on the overall carbon-carbon material system. Models will be used to investigate the effects of inhibitors, microcrack patterns, fiber coatings, surface coatings, and matrix replacements on effective thermomechanical properties of carbon-carbon materials. The result of these models will allow the quantification of effective crack management strategies to improve the overall performance of these materials. Parallel efforts in this program include an experimental portion for the quantification of microcracks within the material and a variety of thermomechanical tests on specimens with and without coatings and inhibitors. Different material systems will allow a full range of constituent and processing variables to be studied. Results of these experiments will be compared to the predictions of the mathematical models in order to suggest improved design methods for carbon. DTIC

ENVIRONMENT ENHANCED FATIGUE CRACK PROPAGATION IN METALS: INPUTS TO FRACTURE MECHANICS LIFE PREDICTION MODELS Final Report
Richard P. Gangloff and Sang-Shik Kim Sep. 1993 224 p
(Grant NAG1-745; RTOP 510-02-12-10)
(NASA-CR-191538; NAS 1.26:191538) Avail: CASI HC A10/MF A03

This report is a critical review of both environment-enhanced fatigue crack propagation data and the predictive capabilities of crack growth rate models. This information provides the necessary foundation for incorporating environmental effects in NASA FLAGRO and will better enable predictions of aerospace component fatigue lives. The review presents extensive literature data on 'stress corrosion cracking and corrosion fatigue.' The linear elastic fracture mechanics approach, based on stress intensity range (Delta(K)) similitude with microscopic crack propagation threshold and growth rates, provides a basis for these data. Results are presented showing enhanced growth rates for gases (viz., H2 and H2O) and electrolytes (e.g. NaCl and H2O) in aerospace alloys including: C-Mn and heat treated alloy steels, aluminum alloys, nickel-based superalloys, and titanium alloys. Environment causes purely time-dependent accelerated fatigue crack growth above the monotonic load cracking threshold (KIEAC) and promotes cycle-time dependent cracking below (KIEAC). These phenomenon are discussed in terms of hydrogen embrittlement, dissolution, and film rupture crack tip damage mechanisms. Author (revised)

STRUCTURAL AND DYNAMICAL ASPECTS OF ELECTRODEPOSITION Final Report, 26 Feb. 1990 - 15 Feb. 1993
Hector D. Abruna May 1993 6 p
(Contract DAAL03-90-G-0048)
(AD-A266786; ARO-27502.4-CH) Avail: CASI HC A02/MF A01

The basic aim of this contract was to investigate structural and dynamical aspects of electrochemical phase formation. In these investigations we have emphasized the underpotential deposition of metal mono and multilayers employing electrochemical, x-ray based and ultra high vacuum surface spectroscopic techniques. We have been able to study: (1) The underpotential deposition of silver on a Pt(111) electrode as function of concentration, potential sweep rate, the presence of co-adsorbates. From these studies we have been able to determine that two monolayers of silver are deposited at underpotentials and that the stability of the second layer is a strong function of the concentration of silver in solution and the potential sweep rate. The presence of co-adsorbates can have a profound influence in the deposition and the magnitude of this effect(s) is strongly dependent on the type of adsorbate employed. (2) The underpotential deposition of copper on an iodine covered platinum surface by x-ray based techniques with emphasis on: isotherms derived from electrochemical and x-ray based measurements, mode of deposition, structure of the copper layer. We have found that isotherms derived from x-ray based measurements consistently yield a significantly higher coverage (relative to electrochemically derived isotherms) that we ascribe to copper species weakly associated with the interface. We have also found that the deposition appears to obey a mechanism where sites deeper in the platinum surface are occupied first and that sites further up are the progressively occupied. The structure of the copper appears to be strongly influenced by the chemisorbed iodine. The copper atoms appear to occupy bridge sites on the surface. DTIC

A total of 40 individually funded tasks were performed under this effort. These tasks were concerned with many fuel analysis and combustion research, conducted for the Fuels Branch (WL/POSF), Lubrications Branch (WL/POSL) and other Aero Propulsion and Power Directorate Laboratories. This report is a compilation of 1-2 page summaries from each of the tasks. More information on each task is available in the technical reports, journal articles, letter reports or informal information listed for the project. Although the subjects covered under this contract are too varied to list here, the most often addressed areas were research topics in gas chromatography and related instrumentation, thermal stability testing and methods development, lubrications research and combustion studies. The van der Waals complex OH-Kr was detected in a free jet expansion by laser-induced fluorescence (LIF) near the (1,0) band of the A(sup 2)Sigma(+) reverse yields X(sup 2)Pi(sub i) transition of uncomplexed OH. The excitation spectrum reveals a progression of vibrational bands which were assigned to the stretching motion of the complex. A Birge-Sponer plot at this progression yields a fundamental frequency of omega(sup prime)(sub c) = 196 +/- 8 cm(sup -1) and an anharmonicity constant of omega(sup prime)(sub c)Xi(sup prime)(sub c) = 7.4 +/- 0.7 cm(sup -1) for the A(sup 2)Sigma(+) excited state. The lower limit of the binding energy of the complex is measured as D(sup prime)(sub o)(nu(sup prime) = 1) is greater than or equal to 1,131 cm(sup -1). These results are compared to those obtained from recent gas-phase LIF studies on the OH-Ne and OH-Ar complexes near the A(sup 2)Sigma(+) reverse yields X(sup 2) Pi(sub i) (0,0) and (1,0) bands of OH, respectively, and those from a matrix LIF study on the OH-Kr complex near the (2,0) band of OH. THE THERMAL DISSOCIATION OF NH2CHO(ND2CHO) ON Si(100)-2X1 Technical Report No. 20
Y. Bu and M. C. Lin 21 Jul. 1993 27 p Submitted for publication
(Contract N00014-89-J-1235)
(AD-A266903) Avail: CASI HC A03/MF A01

The interaction between NH2CHO(ND2CHO) and Si(100)-2x1 was investigated using HREELS, UPS, and XPS. At 100 K, formamide molecules randomly adsorbed on the surface, but became ordered, likely with the O-atom attached to the surface, as the 2 L NH2CHO dosed Si(100) surface

was warmed to 220 K. At this temperature, the formation of some Si-H species is indicated by the appearance of the 256 meV peak due to Si-H stretching vibration in HREELS. When the sample was annealed at 450 K, the OH and more H species were formed. In addition, a peak at 172(160) meV appeared in HREELS, which could be attributed to the HN=C (DN=C) and/or HNCO (DNCO) species. The latter species is more clearly evident in the UP spectrum. At 550 K, the breaking of CH, NH, and probably some OH bonds continued and the OH and H dominated the adspecies. Further annealing the sample at higher temperatures caused the formation of Si-O-Si complex as indicated by the 129 meV peak in HREELS due to the asymmetric stretching mode of the Si-O-Si species. Above 800 K, the Si-H stretching mode at 260 meV decreased dramatically because of the desorption of the H-species. DTIC

The Experimental Research Branch of the Advanced Propulsion Division at Wright-Patterson Air Force Base began taking steps toward the development and installation of a supersonic combustion research facility during FY-90. A large-scale in-house research facility devoted to the study of supersonic fuel air mixing and combustion has been designed, fabricated, and installed. The purpose of the report that follows is to present documentation of the features of the air supply system, the design details and the characteristics of the actual supersonic combustion tunnel, and a description of the control system and instrumentation. THEORETICAL PREDICTION OF THE UV ADSORPTION AND FLUORESCENCE SPECTRA OF TYROSINE AND PHENYLALANINE Final Report, May - Aug. 1992
Hendrik F. Hameka and James O. Jensen May 1993 22 p
(Contract DAAL03-91-C-0034)
(AD-A266970; ERDEC-TR-059) Avail: CASI HC A03/MF A01

This report presents a theoretical study of the ground state and of the first excited state of phenylalanine and tyrosine to interpret the excitation absorption and the fluorescence emission spectra of the two molecules. The computations are performed with the Gaussian 90 Program Package using 3-21G basis sets. The ground state is computed with the HF option and the excited state with the Configuration Interaction, Single (CIS) Excitations option only. This report optimized the molecular geometries of both the ground and excited states and computed the excitation energies at both geometries. In conclusion, the excited state is due to a superposition of excitations from bonding orbitals in the alanine chain to a pi orbital in the benzene ring and to an orbital in the C-C bond attached to the ring. REACTION AND DIFFUSION IN TURBULENT COMBUSTION
S. B. Pope 18 Jun. 1993 37 p
(Contract DE-FG02-90ER-14128)
(DE93-017085; DOE/ER-14128/T1) Avail: CASI HC A03/MF A01

A class of turbulent combustion models known as PDF methods has been developed. These methods have the important virtue that both convection and reaction can be treated without turbulence-modelling assumptions. However, a mixing model is required to account for the effects of molecular diffusion. Currently, the available mixing models are known to have some significant defects. Motivation of the project is to seek a better understanding of molecular diffusion in turbulent reactive flows; and thereby to provide guidance to the development of improved mixing models. Principal approach taken in the research is to use Direct Numerical Simulations (DNS) to study the coupled processes of reaction and molecular mixing in turbulent combustion. Because of inevitable computational limitations, it is impossible to simulate turbulent combustion in the parameter range of practical interest. Instead, our approach is to study very simple turbulent reactive flows that contain qualitatively some of the same phenomena as real flames. Statistical models will be developed that are applicable to practical combustion devices. The DNS studies related to non-premixed combustion are described. An additional topic studied, was mixing from the viewpoint of relative molecular motion. DOE

SOUNDING ROCKET EXPERIMENTS IN FLUID SCIENCE AND MATERIALS SCIENCES: TEXUS 25 TO 27 AND MASER 4, VOLUME 3 Final Reports
Olivier Minster and Brigitte Kaldeich, ed. Feb. 1993 133 p Original contains color illustrations
(ESA-SP-1132-Vol-3; ISBN-9-29-092104-8; ETN-93-94426) Copyright Avail: CASI HC A07/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Experiments in materials and fluid sciences carried out during the flights of the sounding rocket TEXUS 25, 26, and 27 and MASER 4, all in 1990, are reported. The following topics are discussed: Measurement of Interfacial Tension (MITE); the onset and flow pattern of magnetic Benard convection; pool boiling heat transfer; ultrasound absorption in molten salts; orientation of DNA during free solution electrophoresis; electrophoresis visualization; density and temperature relaxation near the critical point of CO2; temperature propagation in near critical fluids prior to and during separation; pressures of supercritical salt solutions; unidirectional solidification of liquid crystal material; partial melting of Y-Ba-Cu oxide; remelting of Fe-C-Si alloy in a ceramic mold; separation behavior of monotectic alloys; liquid phase sintering of tungsten composites; and the behavior of the energy storage material, LiF. For individual titles, see N94-15158 through N94-15172.

The MITE experiment was flown on MASER 4 in Mar. 1990. The aim of the experiment was to test in microgravity a new method called the Pressure Derivative (PD) method. The PD method was developed to measure interfacial tension of couples of liquids and is applicable in conditions where the Bond number (Bo) equals zero. The methodology of the PD method is outlined. The flight experiment is described and results and conclusions are given. It was found that the behavior of the module was satisfactory, and it allowed us to measure values of the interfacial tension of the water/alpha-BromoNaphtalene couple which are in good agreement with values found on ground for the same materials. It is pointed out that the experimental signal recorded in space is much smoother and less disturbed than the ones recorded on ground. ESA

BENARD CONVECTION OF MAGNETIC COLLOIDS UNDER MICROGRAVITY c29
S. Odenbach *In* ESA, Sounding Rocket Experiments in Fluid Science and Materials Sciences: TEXUS 25 to 27 and MASER 4, Volume 3 Feb. 1993 p 16-23 (For primary document see N94-15157 03-25)
Copyright Avail: CASI HC A02/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The onset and the flow pattern of magnetic Benard convection under reduced gravity were investigated. This Benard convection is a form of thermal convection which can be induced in a magnetizable fluid even without gravity. This is possible when suitable magnetic fields are applied. The experiment consists of two concentric hollow cylindrical containers. The cylindrical gap between the containers is filled with ferrofluid (a suspension of small magnetite particles in an appropriate solute). The gap is heated from its inner wall and cooled on the outer surface. This special geometry establishes periodic boundary conditions. Those boundary conditions are not feasible in a ground based experiment, but they are very important for theoretical investigations. The flow profile was investigated as a function of the strength of the applied magnetic fields. Magnetic convection was clearly observed in a microgravity experiment flown with a TEXUS sounding rocket flight in Spring 1990. ESA

POOL BOILING: SINGLE BUBBLE EXPERIMENT **c29**

B. Vogel and J. Straub *In* ESA, Sounding Rocket Experiments in Fluid Science and Materials Sciences: TEXUS 25 to 27 and MASER 4, Volume 3 Feb. 1993 p 24-34 Sponsored by BMFT (For primary document see N94-15157 03-25)

Copyright Avail: CASI HC A03/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

To gain new knowledge about pool boiling heat transfer in microgravity and on Earth, single bubble experiments were made in the frame of the TEXUS program. By combining conventional and optical measuring techniques, the governing heat transport mechanisms should be detected. Data about bubble growth, heater temperatures, and temperature profiles close to the bubble, show that for subcooled boiling in microgravity, evaporation is the primary heat transport mechanism, and establishes together with the secondary mechanisms condensation and Marangoni flow, a steady state heat transfer. ULTRASOUND ABSORPTION IN MOLTEN SALTS **c71**

E. P. Rejek, J. Richter, L. Schoester, and M. Vogt *In* ESA, Sounding Rocket Experiments in Fluid Science and Materials Sciences: TEXUS 25 to 27 and MASER 4, Volume 3 Feb. 1993 p 36-41 (For primary document see N94-15157 03-25)

Copyright Avail: CASI HC A02/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

Measurements of ultrasound absorption in liquids show values that exceed the classical values calculated from viscosity and heat conduction by one order of magnitude. In terrestrial experiments, absorption in binary nitrate melts as a function of composition, temperature, and frequency was investigated with the pulse transmission method and the Debye-Sears method. The disturbances caused by convection led to this experiment under microgravity conditions, in order to perform precise reference measurements. The results of three TEXUS experiments showed, however, that the absorption was 20 percent, respectively 15 percent higher. In this third microgravity experiment (TEXUS 25) no significant difference between microgravity and terrestrial values could be found, whereas lower absorption was expected. This new microgravity effect is to be confirmed in further experiments. ESA

ORIENTATION OF DNA DURING FREE-SOLUTION ELECTROPHORESIS **c29**

Mats Jonsson, Ulf Jacobsson, Bengt Norden, and Tore Eriksson *In* ESA, Sounding Rocket Experiments in Fluid Science and Materials Sciences: TEXUS 25 to 27 and MASER 4, Volume 3 Feb. 1993 p 42-52 Sponsored by Swedish Board for Space Activities (For primary document see N94-15157 03-25)

Copyright Avail: CASI HC A03/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The orientation of deoxyribonucleic acid (DNA) during electrophoresis in a free solution under microgravity conditions was studied in a sounding rocket flight with a microgravity time of about 7 minutes. The orientation was detected by Linear Dichroism (LD) spectroscopy utilizing a phase modulation technique. The aim of the experiment was to determine whether microgravity conditions, as an effect of absence of gravity induced convection, would lead to results different from those on the ground regarding the orientational response to electrophoresis in a solution. Duplex T2 DNA (170,000 basepairs) was subjected to rectangular pulses of field strengths between 10 and 100 V/cm. Each pulse has a duration of 30 seconds and the field free time between the pulses was 20 seconds. At the higher field strengths the rise profile of the DNA orientation displays a pronounced overshoot before it reaches a steady state, a behavior which confirms observations in experiments on the ground that the build up of the orientation occurs via a state of high orientational order. The degree of steady state orientation and the amplitude of the orientation overshoot both increase with field strength. However, the orientation is low (S about 0.006 at 100 V/cm). The orientational decay in the absence of field appears to be somewhat slower the higher the field strength of the pulse. However, the signal to noise ratio of the measurement was low, and the LD baseline also varied during the flight, which obviated safe conclusions about the detailed behavior of the DNA and a reliable comparison with ground experiments. Therefore, further experiments with improved equipment are necessary before a final assessment of the relevance of microgravity for the study of electrophoretic orientation of DNA can be made. ESA

An experiment based on Continuous Flow Electrophoresis (CFE), a process that permits purifying or separating products, such as proteins or cells, flown in TEXUS 27 in 1990, is reported. TEXUS provides only about 6 minutes of microgravity conditions, and specific equipment was used to get relevant information. During the CFE process certain phenomena are observed which can modify the originally cylindrical shape of the injected stream that contains the species to be separated, thus resulting in a loss of resolution. Such phenomena are Poiseuille flow, electroosmosis, and electrohydrodynamics. The experiment described was aimed at studying different kinds of transport phenomena. It was found that by working with alternating current the electrohydrodynamic phenomena could be studied without any inference with the other ones. With a direct current, the coupling of electrohydrodynamic with all other phenomena could be assessed. The experimental design is described and results and conclusions given. ESA

In order to investigate the different aspects of the transport of heat and mass in the absence of gravity, a thermal cycle was performed close to and around the critical point of CO2 at critical density. A cell was designed which allows surface and bulk phenomena to be distinguished. Special optical devices were used to observe the sample and measure locally temperature and density. Experiments under Earth's gravity a few mK close to the critical temperature (T(sub C)) are first presented. They enable convection patterns to be observed and a Grashof number as large as 100,000 to be measured. The thermal cycle of the experiment in weightlessness starts at T(sub C) + 2 mK, where the relaxation of the perturbations caused by liftoff are studied: fluid flows, density and temperature gradients. The effect of a quench from T(sub C) + 2 mK to T(sub C) + 1 mK then at T(sub C) - 1 mK and then again at T(sub C) + 2 mK were performed and observations given. ESA

Temperature propagation in a near critical fluid sample (SF6) was

experimentally studied under reduced gravity in space. The experiment was carried out in the TEXUS sounding rocket and light scattering was used to observe the beginning of the gas liquid phase separation and to follow its development. The separation was recorded by video. Onset of phase separation was indicated by the appearance of a spinodal scattering ring. Critical speeding up of temperature equilibration prior to phase separation and markedly slowed down temperature equilibration during phase separation were observed. ESA

It is hypothesized that the gravitational field of the Earth results in such severe sedimentation of sodium chloride solutions that the apparent critical temperatures are increased above their true, zero g, values. If this is true, then gravitational effects offer an explanation for the apparent violation of universality in the critical behavior of sodium chloride solutions. Experiments, designed to test this hypothesis in an independent manner using a technique which is easier to interpret than inductance and which has a direct bearing on the rather uncertain p, V, T properties, are addressed. The concept of the experiment was quite simple. If a solution is just above its true, zero g, critical point and the Earth's gravitational field is sufficient to induce a phase separation, then this change must cause a transfer of particles from the 'vapor' to the liquid phase with a consequent reduction in the pressure. The experiment was designed to look for an increase in pressure as a consequence of the reverse procedure of going from the Earth's gravity to microgravity. With a solution 0.001 M in sodium chloride at a density of 0.313 and a temperature of 377.5 C there was no detectable increase in pressure in going to microgravity. Under the conditions of the experiment, the detection limit would have been 3 bar. Potentially, the system is much more sensitive but to achieve its potential, the temperature overshoot would have to be much reduced and a longer period for thermal equilibration probably allowed. Also, heat flows would probably need to be more carefully controlled. If the experiment were to be repeated, it would almost certainly be desirable to use a cell temperature nearer to 375 C, a larger concentration and a lower mean density. ESA

The process of the advancing interface and the adjacent region of the fluid during unidirectional solidification of liquid crystal material was investigated using polarization microscopy and interferometry. In the isotropic-nematic interface, some wavy patterns were observed and the existence of different mechanisms at different gravity levels was identified. In front of the nematic-solid interface, microconvection, which was recognized on the ground, disappeared under microgravity conditions. The effect of gravity on thermal transport and phase transition using a liquid crystal material as a unique model material is discussed. ESA

PARTIAL MELTING EXPERIMENT OF Y-Ba-Cu OXIDE **c29**
Akira Yoshinari, Akira Okayama, H. Kodama, and N. Hamano *In* ESA, Sounding Rocket Experiments in Fluid Science and Materials Sciences: TEXUS 25 to 27 and MASER 4, Volume 3 Feb. 1993 p 100-109 (For primary document see N94-15157 03-25)
Copyright Avail: CASI HC A02/MF A02; ESA, EPD, ESTEC, Noordwijk, Netherlands, HC

The samples A (Y rich) and the samples B (Cu rich), made of two different compositions of Y-Ba-Cu-O high temperature superconducting alloy, were partially melted either under microgravity in the sounding rocket MASER or on the ground for reference. After partial melting and solidification in microgravity, Y-Ba-Cu-O samples require heat treatment on the ground. Whether a possible effect of microgravity remains after this heat treatment was studied to give a guideline for the selection of materials for future microgravity experiments. The properties of the samples were therfore investigated again after heat treatment. A comparison between samples A and B was made and results concerning the following properties are given: microstructure, superconductive transition temperature, specific resistance, critical current density, and phase distribution. While the samples A partially melted on Earth and in microgravity showed the same microstruture, the samples B had clearly different structures. The sample B partially melted on Earth showed a structure difference between its top and its bottom as Y2O3 and YBa2CuO6 phases segregated towards the bottom, and BaCu2O2 towards the top. In contrast, after melting under microgravity, Y2O3, YBa2Cu3O6, and BaCuO2 phases are distributed uniformly on the sample. After heat treatment, all samples had the same superconductive transition temperature. However, above the transition temperature, the samples A and B had smaller specific resistance when processed on Earth. After sintering at 1213 or 1238 K, the ground reference sample A exhibits a larger critical current density than the flight sample A. The same holds for samples B, but only after heat treatment at 1238 K. Critical current densities in samples B after heat treatment at 1213 K are comparable. ESA

Liquid phase sintering of tungsten heavy metals, which are composites consisting of tungsten particles in a Ni-Fe-W matrix, was investigated under microgravity in TEXUS sounding rockets. Tungsten heavy metals are fabricated from powders by liquid phase sintering, during which the tungsten particles grow in the liquid matrix phase. Experiments were performed in which the surface tension between the molten matrix and the tungsten particles was varied. The heavy metal matrix composition is optimized to a Ni/Fe ratio at which tunsgten particles are effectively separated from each other by the liquid phase during sintering. By using other matrix compositions, the separation and growth processes can be influenced. The addition of a small amount of sulphur to the matrix will decrease the surface tension while a nickel matrix increases the tension. Such matrix compositions were used for the study of liquid phase sintering under microgravity. TEXUS flight experiments were used to achieve up to 5 minutes of liquid phase sintering under microgravity. To study the effect of surface tension between the molten matrix and the tungsten particles, short time tests of these systems during parabolic flights were performed. The results of the parabolic flight and TEXUS 26 and 27 experiments are evaluated. ESA

Experiments performed on TEXUS 27 sounding rocket to investigate the thermal energy storage module of solar dynamic systems are reported. One of the most suitable energy storage materials for the desired temperature range of 800 to 900 C is lithium fluoride (LiF). Due to the large volume increase during melting of approximately 22% and the corrosivity in the molten state, a canister made of graphite or glass carbon was developed for space use. The heat exchanging wall is equipped with channels and the canister is filled in such a way that molten LiF occupies the whole volume except the channels. In the discharge model, the crystallization of LiF starts at the outer wall and continues towards the center of the canister. There, a void forms due to the volume contraction. The next melting cycle starts again at the heat exchanging wall, and the surplus of volume, due to the pressure of the central void, is able to penetrate the channels against the capillary forces. As soon as the melting front reaches the void, the capillary forces drive the melt out of the channels and a new cycle can start. Tests under terrestrial conditions revealed that the melt did not penetrate the channels as long as the gravity dependent pressure did not exceed the capillary pressure. The TEXUS experiments reported were performed to clarify the following points under microgravity: the melting/freezing behavior of LiF; the formation of the void(s) (Does one void form or several voids? Where is the void located? If several voids are generated, how is their distribution?); and the predicted function of the volume compensation. ESA

THE PRESSURE BROADENING OF HDO BY O2, N2, H2, AND He BETWEEN 100 K AND 600 K
Thomas M. Goyette, David W. Ferguson, Frank C. DeLucia, Jyotsna M. Dutta, and Charles R. Jones 30 Jun. 1993 26 p
(Contract F49620-89-C-0080)
(AD-A267118; AFOSR-93-0540TR) Avail: CASI HC A03/MF A01

Microwave transitions of HDO pressure-broadened by H2, O2, N2, and He were studied in the temperature region between 100 and 600 K. Measurements below 250 K were made in a collisionally cooled cell. Above this temperature a conventional equilibrium cell was used in the region where the HDO has non-negligible vapor pressure. Significant variations in both the pressure broadening parameter and its temperature dependence were observed among the studied transitions. Ordinarily, a power law is used to describe this temperature dependence. Deviations from this were observed below 150K. DTIC

SPECTRAL STUDIES OF SOLID PROPELLANT COMBUSTION 4: ABSORPTION AND BURN RATE RESULTS FOR M43, XM39, AND M10 PROPELLANTS Final Report, 1 Jun. - 31 Dec. 1992
M. W. Teague, Gurbax Singh, and John A. Vanderhoff Aug. 1993 28 p
(DA Proj. 1L1-61102-AH-43)
(AD-A267119; ARL-TR-180) Avail: CASI HC A03/MF A01

An optical absorption experiment coupled to a windowed strand burner has been used to obtain dark zone temperatures and nitric oxide concentrations for two nitramine propellants (M43 and XM39) and a single base propellant (M10). Moreover, burn rates as a function of pressure were determined from the video record of the propellant burns. These measurements were taken over a pressure range from 0.8 to 2 MPa. DTIC

STUDY OF PROTEIN-H2O INTERACTIONS BY MULTIDIMENSIONAL NMR SPECTROSCOPY Report, 1 Apr. 1991 - 31 Mar. 1993
Rachel E. Klevit Jul. 1993 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1766)
(AD-A266955) Avail: CASI HC A02

Water has been shown to play an integral role in both structural and catalytic aspects of protein function. Strongly-bound water molecules are observed in high-resolution protein structures by x-ray diffraction studies of single crystals of protein molecules. The pilot studies described here were aimed at ascertaining the feasibility of detecting strongly-bound water molecules in solution using multidimensional heteronuclear NMR spectroscopy. Three dimensional -(1H, 15N)-HMQC-ROESY spectroscopy was implemented on a Bruker AM-500 spectrometer and spectra were collected on a series of related HPr protein molecules. Interactions involving both H20 and -OH groups were reproducibly detected in the spectra. The results indicate that this approach is capable of yielding a limited amount of information concerning protein-water interactions and is not likely to become a generally-used technique. DTIC

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF THE FEASIBILITY OF ACCELERATED LIFETIME TESTING OF MATERIALS EXPOSED TO AN ATOMIC OXYGEN BEAM Final Report
Royal Albridge, Alan Barnes, and Norman Tolk 11 Jun. 1993 48 p
(Contract NAS8-37744)
(NASA-CR-193851; NAS 1.26:193851) Avail: CASI HC A03/MF A01

The interaction of atomic particles with surfaces is of both scientific and technological interest. Past work emphasizes the measurement of high-energy sputtering yields. Very little work utilized low-energy beams for which chemical and electronic effects can be important. Even less work has been carried out using well-defined low-energy projectiles. The use of low-energy, reactive projectiles permits one to investigate surface processes that have not been well characterized. As the energy of the projectile decreases, the collisional cascades and spikes, that are common for high-energy projectiles, become less important, and chemical and electronic effects can play a significant role. Aspects of particle-surface interactions are of concern in several areas of technology. For example, the erosion, desorption, and glow of surfaces of spacecraft in orbit are important in the

arena of space technology. The materials studied under this contract are of possible use on the exterior portions of the power generation system of Space Station Freedom. Under the original designs, Space Station Freedom's power generation system would generate potential differences on the surface as high as 200 volts. Ions in the plasma that often surround orbiting vehicles would be accelerated by these potentials leading to bombardment and erosion of the exposed surfaces. The major constituent of the atmosphere, approximately 90 percent, in the low earth orbit region is atomic oxygen. Since atomic oxygen is extremely reactive with most materials, chemical effects can arise in addition to the physical sputtering caused by the acceleration of the oxygen ions. Furthermore, the incident oxygen ions can remain embedded in the exposed surfaces, altering the chemical composition of the surfaces. Since the effective binding energy of a chemically altered surface can be quite different from that of the pure substrate, the sputtering yield of a chemically altered surface is usually different also. The low-energy O+ sputtering yield measurements, reported here, will help quantify the erosion rates for materials exposed to the low-earth orbit environment. These measurements are of technological importance in another respect. In most surface analysis techniques, a surface is bombarded with ions, electrons or photons. Information concerning the structure of the surface and near-surface bulk, abundance of impurities and defects, as well as other surface properties are obtained either from the desorbed species or from the scattered projectiles. Because of their low penetration depth, low-energy ions provide an advantage over other techniques because they provide information that is more indicative of conditions on the surface rather than integrated effects arising from deeper in the bulk. A better understanding of the microscopic processes involved in these interactions is not only of basic scientific interest, but will also aid the scientific community by increasing the accuracy and usefulness of these surface analysis techniques. GAS SEPARATIONS USING CERAMIC MEMBRANES
C. L. Lin, J. C. S. Wu, G. R. Gallaher, G. W. Smith, D. L. Flowers, T. E. Gerdes, and P. K. T. Liu Feb. 1993 203 p
(Contract DE-AC21-88MC-25135)
(DE93-000278; DOE/MC-25135/3341) Avail: CASI HC A10/MF A03

This study covers a comprehensive evaluation of existing ceramic membranes for high temperature gas separations. A methodology has been established for microporous characterization stability and gas separation efficiency. A mathematical model was developed to predict gas separations with existing membranes. Silica and zeolitic modifications of existing membranes were pursued to enhance its separation efficiency. Some of the membrane modifications demonstrate unique separation properties. Use of the dense-silica membranes for hydrogen enrichment was identified as a promising candidate for future development. In addition, the decomposition of trace ammonia contaminant via a catalytic membrane reactor appears feasible. A further economic analysis is required to assess its commercial viability. DOE

IN SITU STUDIES OF PASSIVE FILM CHEMISTRY USING X RAY ABSORPTION SPECTROSCOPY
A. J. Davenport, H. S. Isaacs, J. A. Bardwell (National Research Council of Canada, Ottawa, Ontario.), and B. MacDougall (National Research Council of Canada, Ottawa, Ontario.) 1993 8 p Presented at the 12th International Corrosion Congress, Houston, TX, 19-24 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014023; BNL-48665; CONF-9309150-1) Avail: CASI HC A02/MF A01

The passive film on sputter-deposited thin film Fe and Fe-26Cr electrodes has been examined using in situ X-ray Absorption Near Edge Spectroscopy (XANES). During the x-ray spectroscopic measurements, samples were maintained under potentiostatic control in pH 8.4 borate buffer. The passive film on both Fe and Fe-26Cr is formed from the metal without any detectable losses due to dissolution. Cathodic reduction leads to a loss of Fe from the film in both cases, but substantially less Fe is lost in the case of Fe-26Cr. Transpassive dissolution of Cr from Fe-26Cr only occurred on the second potential cycle after the film had been enriched in Cr due to the reductive dissolution of Fe. Simultaneous collection of both the Fe and Cr x-ray absorption edges provides quantitative information on the relative amounts of material lost during passivation and reduction. DOE

APPLICATION OF Z-CONTRAST IMAGING TO OBTAIN COLUMN-BY-COLUMN SPECTROSCOPIC ANALYSIS OF MATERIALS
N. D. Browning and S. J. Pennycook Jan. 1993 7 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015333; CONF-921101-125) Avail: CASI HC A02/MF A01

Z-contrast imaging has been shown to be an effective method for obtaining a high-resolution image from a scanning transmission electron microscope (STEM). The incoherent nature of the high-angle scattering makes image interpretation straightforward and intuitive with the resolution limited only by the 2.2 A electron probe. The optimum experimental conditions for Z-contrast imaging also coincide with those used for analytical microscopy, enabling microanalysis to be performed with the same spatial resolution as the image. The detection limits afforded by a parallel detection system for electron energy loss spectroscopy (EELS) allows column-by-column core-loss spectroscopy to be performed using the Z-contrast image to position the electron probe. Preliminary results from the study of YBa2Cu3O(7-delta) illustrate the spatial resolution available with this technique and the potential applications for materials science. DOE

A COMPARISON OF ONE AND TWO DIMENSIONAL FLAME QUENCHING: HEAT TRANSFER RESULTS
O. A. Ezekoye and R. Greif Mar. 1993 10 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract DE-AC03-76SF-00098)
(DE93-015196; LBL-33817; CONF-930830-22) Avail: CASI HC A02/MF A01

A theoretical investigation of laminar premixed flame quenching is carried out. Two orientations in which a flame may contact a cold wall are compared and contrasted by solving the conservation equations of mass, energy, and species utilizing a finite difference methodology. A one-step mechanism is used to specify the reaction rates. A simple analytical model, which is in qualitative agreement with the numerical results, is also presented. The results show that the heat transfer histories for one and two dimensional laminar flame quenching are similar. DOE

CORROSION KINETICS AND MECHANISMS FOR NUCLEAR GRADE GRAPHITES
L. E. Fuller, Jr., O. C. Kopp, and A. D. Underwood 1993 17 p Presented at the NACE Annual Corrosion Conference and Materials Performance and Corrosion Show, New Orleans, LA, 7-12 Mar. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015462; CONF-930318-10) Avail: CASI HC A03/MF A01 (US Sales Only)

An initial microgravimetric evaluation of the intrinsic reaction parameters for air reactions with H-451 graphite at 375 to 850 C at atmospheric pressure and for water contents from 0 to 2 vol% water vapor is reported. Photographic results show heterogeneous nature of the graphite and consequential variation of reaction rate as the samples are etched and

roughened in the corrosion processes. The reaction rate increases approximately two fold to a near-constant value and subsequently approaches zero as the remnant skeletal matrix is consumed. There appears to be no significant rate effect (neither catalytic nor impedimental) due to the presence of water vapor in the concentrations used. DOE

STUDIES OF COMBUSTION REACTIONS AT THE STATE-RESOLVED DIFFERENTIAL CROSS SECTION LEVEL
P. L. Houston 12 Apr. 1993 5 p
(Contract DE-FG02-88ER-13934)
(DE93-017605; DOE/ER-13934/T1) Avail: CASI HC A01/MF A01

This program explores a new technique for obtaining differential cross sections with product state resolution. The three-dimensional velocity distribution of state-selected reaction products is determined by ionizing the appropriate product, waiting for a delay while it recoils along the trajectory imparted by the reaction, and finally projecting the spatial distribution of ions onto a two dimensional screen using a pulsed electric field. Knowing the arrival time allows the ion position to be converted to a velocity, and the density of velocity projections can be inverted mathematically to provide three-dimensional velocity distribution for the selected product. Apparatus has been constructed and tested using photodissociations. The proposed research will both develop the new technique and employ it to investigate methyl radical, formyl radical, and hydrogen atom reactions which are important in combustion processes. We intend specifically to characterize the reactions of CH3 with H2 and H2CO; of HCO with O2; and of H with CH4, CO2 and O2. DOE

WATER ADSORPTION ON DIAMOND (110) STUDIED BY MULTIPLE INTERNAL REFLECTION INFRARED SPECTROSCOPY
M. McGonigal, J. N. Russell, Jr., P. E. Pehrsson, H. Maguire, and J. E. Butler 14 Jun. 1993 20 p
(AD-A266415; NRL/MR/6174-93-7351) Avail: CASI HC A03/MF A01

The adsorption of water on a natural, type 2a diamond (110) surface is studied by multiple internal reflection infrared spectroscopy (MIRIRS). Similar results are observed for the hydrogen-free, and hydrogen-terminated diamond (110) surfaces. Exposure of water at 100 K reveals the presence of physisorbed molecular water on the surface, with no evidence of dissociation. Upon heating to approximately 160 K, the water is desorbed from the surface without any evidence of chemisorption or decomposition. Exposure of the surface to water at elevated temperatures (373 and 773 K) also failed to produce any evidence in the infrared spectra of chemisorption or decomposition. However, the absence of water dissociative chemisorption may be the result of sp2 carbon contamination which was found on the surface at the conclusion of the experiments. DTIC

SCINTILLATION MECHANISM IN STOICHIOMETRIC CERIUM COMPOUNDS
A. J. Wojtowicz (Nicolaus Copernicus Univ., Torun, Poland.), A. Lempicki, and E. Berman 1992 5 p Presented at the Crystal 2000 International Workshop on Heavy Scintillators for Scientific and Industrial Applications, Chamonix, France, 22-26 Sep. 1992 Prepared in cooperation with ALEM Associates, Boston, MA
(Contracts DE-FG02-90ER-61033; DE-FG02-92ER-81360)
(DE93-015499; CONF-9209253-5) Avail: CASI HC A01/MF A01

These materials constitute a new class of scintillator media, with high speed and high light output. This is illustrated using CeF3, and CeP5O14. While speed, being limited by a radiative lifetime of an allowed d-f transition on the Ce(+3) ion, cannot be improved (without loss of the light output), the light output in both cases falls significantly below the estimated theoretical limit. To explain this we propose a mechanism of scintillation process, in which transfer of excitation energy from the lattice to the d-f electronic structure of Ce(+3) ions is absent and the light output of the scintillator is limited to the excitation energy directly intercepted by Ce ions. The efficiency depends, therefore, on the competition for holes between Ce(+3) ions and anions, determining the share of the total energy deposited by a high energy particle, which can be transformed into scintillation photons. The mechanism requires that the Ce ion has a stable 4+ charge state. Ionization of Ce(+3) is followed by capturing of an electron and creation of the Ce bound exciton. In the next step the energy of the bound exciton is transferred to the d-f structure of the Ce ion and, in the final step, a scintillation photon is emitted. The relatively high light output characteristic of these materials is due to the high concentration of Ce ions. The reasons for the lack of efficient energy transfer from the lattice may reside in large relaxation energies of lattice excitations. We use this model to discuss potential improvements in the light output of CeF3. DOE

CONVERGENCE OF THE MULTIPLE SCATTERING EXPANSION IN XAFS AND XANES
J. J. Rehr 1992 5 p Presented at the International Workshop on Surface X Ray Absorption Fine Structure (XAFS), Jaipur, India, Aug. 1992
(Contract DE-FG06-90ER-45415)
(DE93-011001; DOE/ER-45415/8; CONF-9208221-1) Avail: CASI HC A01/MF A01

The convergence of the multiple-scattering expansion of XAFS and XANES by explicit path-bypath calculations is discussed. The approach is based on the fast scattering matrix formalism of Rehr and Albers, together with an automated path finder and filters that exclude negligible paths. High-order scattering terms are found to be essential, especially at low energies. Several factors including the magnitude of curved wave scattering amplitudes, inelastic losses and multiple-scattering Debye-Waller factors control convergence of the expansion. The convergence is illustrated explicitly for the case of diatomic molecules. DOE

(Contract DE-AC03-76SF-00098)
(DE93-013890; LBL-33961) Avail: CASI HC A08/MF A02

Gas-phase isothermal chromatography is a method by which volatile compounds of different chemical elements can be separated according to their volatilities. The technique, coupled with theoretical modeling of the processes occurring in the chromatography column, provides accurate determination of thermodynamic properties (e.g., adsorption enthalpies) for compounds of elements, such as the transactinides, which can only be produced on an atom-at-a-time basis. In addition, the chemical selectivity of the isothermal chromatography technique provides the decontamination from interfering activities necessary for the determination of the nuclear decay properties of isotopes of the transactinide elements. Volatility measurements were performed on chloride species of Rf and its group 4 homologs, Zr and Hf, as well as Ha and its group 5 homologs, Nb and Ta. Adsorption enthalpies were calculated for all species using a Monte Carlo code simulation based on a microscopic model for gas thermochromatography in open columns with laminar flow of the carrier gas. Preliminary results are presented for Zr- and Nb-bromides. DOE

BINDING OF CARBON DIOXIDE TO METAL MACROCYCLES: TOWARD A MECHANISTIC UNDERSTANDING OF ELECTROCHEMICAL AND PHOTOCHEMICAL CARBON DIOXIDE REDUCTION
E. Fujita 1993 10 p Presented at the International Conference on Carbon Dioxide Utilization, Bari (Italy), 26-30 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE93-016244; BNL-49082; CONF-9309182-1) Avail: CASI HC A02/MF A01

Efforts were made to find effective catalysts for photochemical and electrochemical reduction of CO2. We are studying the factors controlling excited-state lifetimes, electron-transfer rates to mediators/catalysts, properties of reduced mediators, binding of small molecules to reduced mediators, and reactivity of the mediators to yield the desired products. This document describes some of the results of binding on CO2 to metal macrocycles. The electrocatalytic activity of cobalt macrocycle complexes in reduction of CO2 in CO2-saturated water at the Hg electrode is being studied. We are ready to study the mechanism and kinetics of the photochemical CO2 reduction in order to design more efficient photo-energy conversion systems. DOE

GAS ANALYSIS SYSTEM
R. A. Green 1992 64 p
(Contract DE-AC02-80ET-15601)
(DE93-014617; DOE/ET-15601/T56) Avail: CASI HC A04/MF A01

A Gas Analysis System (GAS) has been configured at the Diagnostic Instrumentation and Analysis Laboratory (DIAL) to analyze the gaseous combustion products from nearly any combustion source. GAS is a mobile system of commercially available gas analyzers capable of analyzing a sample for O2, SO2, CO, CO2, NO(x), and combustibles (as %CH4). A Gas Chromatograph is also available as a separate instrument for gas analysis. The analyzers determine the specie concentrations and send a signal to a computer used for data logging. The computer converts the electrical signal into a concentration, stores the data on a disk, displays the results on the computer display, and can also provide a printout of the results. GAS has also had several sampling systems designed for various environments. A sampling system, capable of collecting and storing samples for later analysis, has also been designed. GAS has been used to determine gas compositions at Mississippi State University and the Component Development and Integration facility in Butte, Montana, and at industrial facilities. Computer programs are included. DOE

DIRECT CATALYTIC DECOMPOSITION OF NITRIC OXIDE
M. Flytzani-Stephanopoulos, A. F. Sarofim, and Yanping Zhang 1993 20 p
(Contract DE-FG22-91PC-91293)
(DE93-016689; DOE/PC-91293/T2) Avail: CASI HC A03/MF A01

This project investigates a suitable catalyst system for direct NO decomposition in post-combustion gas streams. The process does not use a reductant, such as the ammonia used in Selective Catalytic Reduction (SCR) of NO(x) to nitrogen. Therefore, it is a greatly simplified process basically involving passing the flue gas through a catalytic converter. Catalysts are prepared by incorporating metal cations into zeolite supports according to ion exchange procedures widely used in preparation of metal/zeolite catalysts. The catalysts of primary interest include copper, palladium, silver, and nickel exchanged ZSM-5 catalysts. Particular emphasis is given in this work on promoted Cu-exchanged zeolites, especially the catalyst system Mg/Cu-ZSM-5 and a few others, which are promising for NO conversion to nitrogen at typical flue gas O2 and NO levels and over the temperature range of 723-873 K. Effects of zeolite modification, copper exchange level and catalyst preparation conditions on the catalyst activity are studied in a packed-bed microreactor. Temperature-programmed desorption (TPD) and reduction (TPR) experiments will be carried out in a thermogravimetric analyzer and a single-particle electrodynamic balance (EDB). Kinetic studies of NO and O2 interaction with catalysts over a wide temperature range as well as catalyst structural investigations are planned. DOE

(Contract DE-AC22-92PC-92110)
(DE93-016850; DOE/PC-92110/T2) Avail: CASI HC A03/MF A01

During the second quarter, we initiated Task 2 (Process and Catalyst Variable Study). This task involves an investigation of methods for vanadium phosphate (VPO) catalyst synthesis and activation as well as detailed testing of the catalysts produced for activity and selectivity in methane selective oxidation. As we initiated work on Task 2, three problem areas were identified: preparation of catalysts with P:V ratio greater than 1; activation of the precursor to produce the B-phase described in the patent literature; and achieving high (greater than 95 percent) carbon balances in the bench-scale test unit. Each of these problems has been addressed and overcome during this quarter. Several catalysts with P:V ratios ranging from 0.95 to 1.1 have been prepared. Activation procedures are continuing to be investigated. We have found several procedures which yield catalysts having the desired X-ray diffraction pattern. The reactor system was modified and analytical procedures improved so that in a 7-day run using V2O5 as the catalyst, carbon balances ranged from 95 to 105 percent. DOE

The authors have measured the ion yields for helium and neon ionized by 120 femtosecond, 614 nanometer laser pulses with intensities up to 10(exp 16) watts per square centimeter. They have found that the He 2 and Ne 2 data exhibit features incompatible with standard nonresonant sequential ionization. These features reduce the usefulness of optical field

ionization for monitoring laser intensity. For the experiment, they expect dynamic resonances to have little effect on the ionization, and they attribute the features to nonsequential ionization based on the simultaneous saturation of the features and the singly ionized charge states. DOE

PRECONVERSION CATALYTIC DEOXYGENATION OF PHENOLIC FUNCTIONAL GROUPS
C. P. Kubiak 1992 19 p
(Contract DE-FG22-89PC-89770)
(DE93-017034; DOE/PC-89770/T14) Avail: CASI HC A03/MF A01

Several new catalysts for phenol deoxygenation by CO were developed in our laboratories during the grant period. The deoxygenation of phenols by CO represents a novel approach to the upgrading of coal liquids. The deoxygenation of phenols by CO is thermodynamically more favorable and potentially less expensive than current phenol hydrodeoxygenation (HDO) methods. The reaction was not known to be kinetically feasible until our recent discovery of appropriate catalysts. The catalyst precursor (Ir(triphos)((eta)(sup 4-))C8H12)(C1) was found to catalytically deoxygenate phenol and p-cresol. Reactions were conducted with varying amounts of Ar-OH (Ar = C6H5, p-Me-C6H4), NaO-Ar, and catalyst precursor. In some reactions, triethyl amine was substituted for NaO-Ar to deprotonate the Ar-OH. All reactions took place at 55 C so that Ar-OH was the solvent. One atmosphere of CO was introduced into each reactor. Periodically, gasses were sampled by gas chromatography (GC) to monitor the disappearance of CO and the appearance of CO2. After the amount of CO2 had reached a plateau, organic products were distilled from the reaction mixture and analyzed by high pressure liquid chromatography (HPLC). Significant quantities of arene (benzene or toluene) were obtained. These results are general. Initial use of phenol results in only benzene. Initial use of p-cresol results in only toluene. Control reactions eliminate the catalyst precursor as the source of CO2 or arene. No evidence is obtained for diarylcarbonate formation. HPLC and GC data consistently demonstrated that toluene and CO2 were the only products obtained from the deoxygenation of p-cresol by CO. These results were extended to a series of variously substituted phenolic and naptholic substrates related to those found in coal liquids. DOE

MODELING STUDY TO EVALUATE THE IONIC MECHANISM OF SOOT FORMATION IN FLAMES Annual Report, 15 Dec. 1991 - 14 Dec. 1992
H. F. Calcote, R. J. Gill, and D. G. Keil Feb. 1993 37 p
(Contract F49620-91-C-0021)
(AD-A266242; TP-518) Avail: CASI HC A03/MF A01

A study is underway to evaluate the proposed ionic mechanism of soot formation by developing a computer model and comparing it with experimental results and with equivalent models based on neutral species. During the present report period both the thermodynamic and reaction kinetic data base for ion-molecule reactions have been updated and expanded. The CHEMKIN-2 flame code, revised last report period, to handle ions is now operating routinely and has bee used to calculate ion profiles for the standard acetylene/oxygen flame. The results are generally in good agreement with experiment, except for the benzotropylium ion, for which the calculated value is about three orders of magnitude less than the experimental value. Poor thermodynamics are suspected. A comparison of data in the literature on the effect of equivalence ratio on acetylene and soot yield with values calculated by thermodynamic equilibrium for a number of fuels show that in general measured acetylene and soot concentrations are far in excess of equilibrium, especially below the threshold soot index. The standard acetylene/oxygen flame seems to be an exception. The results continue to support an ionization mechanism of soot formation. DTIC

AMIDE AND TETRAZENE COMPLEXES OF TRANSITION AND MAIN GROUP ELEMENTS AS PRECURSORS FOR THE LOW TEMPERATURE SYNTHESIS OF ELEMENTAL NITRIDES Final Report, 1 Sep. 1989 - 30 Oct. 1992
William C. Trogler May 1993 3 p
(Grant AF-AFOSR-0408-89)
(AD-A266246; AFOSR-93-0425TR) Avail: CASI HC A01/MF A01

Tetrazene complexes and nitrene compounds derived therefrom were prepared. Attempts to use these compounds as precursors to metal nitride species failed. Metal acetylide complexes were prepared and examined by x-ray crystallography. Electrochemical procedures to deposit aluminum nitride films were explored using nonaqueous solvents. The reaction of several organometallics with azide ion was studied. The disproportionation reactions between 17-electron chromium triad radicals and various nucleophiles were characterized by infrared spectroscopy. The formation of reversible adducts from the reaction between trivalent phosphorus donor ligands and unsaturated organic carbonyl compounds was observed. DTIC

ACTIVATION AND DEACTIVATION OF HIGH CONCENTRATION ARSENIC WITH SOME EVIDENCE OF PRECIPITATION
P. M. Rousseau (Stanford Univ., CA.), P. B. Griffin (Stanford Univ., CA.), J. D. Plummer (Stanford Univ., CA.), and P. G. Carey 29 Dec. 1992 9 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract W-7405-eng-48)
(DE93-016437; UCRL-JC-112521; CONF-930571-21) Avail: CASI HC A02/MF A01

Using box-shaped profiles created by laser melt annealing, the authors investigate the kinetics of arsenic activation and deactivation. They find deactivation shows no history effects which can be consistent either with clustering or precipitation for the cases considered. For activation, they notice it occurs on very short time scales, followed by a slower deactivation process. This is suggestive evidence that at least some precipitation occurs. DOE

TRANSIENT STUDIES OF LOW TEMPERATURE CATALYSTS FOR METHANE CONVERSION
E. E. Wolf 1993 6 p
(Contract DE-FG22-92PC-92529)
(DE93-017710; DOE/PC-92529/T1) Avail: CASI HC A02/MF A01

This report summarizes studies conducted during the past quarter on the partial oxidation of methane on the following catalysts: vanadium phosphate, unsupported and supported on silica, and on the silica (SiO2) support. It was found that the unsupported vanadium phosphate catalyst exhibits some selectivity towards formaldehyde at relatively low methane conversions (up to 5% conversion). The selectivity decreases even further on the silica supported VPO catalyst without a significant increase in conversion. In the case of silica, the reaction temperature decreases, and the formaldehyde selectivity is higher than in the case of the VPO catalyst. DOE

SOLVATIONAL BARRIERS TO INTERFACIAL ELECTRON TRANSFER: MINIMIZATION BY WAY OF VALENCE DELOCALIZATION Technical Report, Jun. - Oct. 1993
Joseph T. Hupp and Xiao L. Zhang 27 Jul. 1993 11 p
(Contract N00014-91-J-1035)
(AD-A267371) Avail: CASI HC A03/MF A01

Standard rate constants (k(sub s)) for interfacial electron transfer (ET) have been obtained for several redox couples featuring very small internal activation barriers. To render these ordinarily fast rates measurable, we have employed low defect density, highly ordered pyrolytic graphite (HOPG) as an electrode material. At the HOPG/aqueous solution interface, we observe - for the first time - the systematic (exponential) increase of k(sub s) with inverse reactant size, predicted by Marcus for electrochemical reactions whose barriers are primarily defined by solvent reorganizational effects. We also observe that rates can be significantly accelerated by delocalizing electrons over multiple metal-centered trapping sites. The degree of rate acceleration is quantitatively consistent with the extent of solvent barrier lowering expected if electronic delocalization effectively increases the radius of the ET reaction site. (AD-A267806; UTRC93-28; AFOSR-93-0592TR) Avail: CASI HC A04

The overall objectives of this work are to (1) refine and update an existing soot formation model and (2) incorporate this soot model into a code describing a laminar, opposed jet diffusion flame. To help advance the understanding of chemical limitations of PAH formation in the soot model, phenylacetylene has been pyrolyzed in a single-pulse shock tube. The formation of PAH's from aromatic-aromatic reactions have been observed and evidence has been obtained for isomerization (equilibration) among polyaromatic species. Thermodynamics of high molecular weight PAH's have been calculated. Benzene production and radiation phenomena have been modeled and where possible these calculations have been compared to experimental results. A sectional aerosol model has been added to the diffusion flame code as well as related subroutines on soot formation, growth, and oxidation and the debugging of the code is nearly complete. Comparisons of the sectional model and a global soot formation model have been made for premixed flames. DTIC

ELECTRON SPECTROSCOPY ANALYSIS Final Technical Report, 13 Apr. 1990 - 12 Apr. 1992
John C. Gregory 1992 10 p
(NASA Order H-01099-D)
(NASA-CR-193591; NAS 1.26:193591; UAH-5-32465) Avail: CASI HC A02/MF A01

The Surface Science Laboratories at the University of Alabama in Huntsville (UAH) are equipped with x-ray photoelectron spectroscopy (XPS or ESCA) and Auger electron spectroscopy (AES) facilities. These techniques provide information from the uppermost atomic layers of a sample, and are thus truly surface sensitive. XPS provides both elemental and chemical state information without restriction on the type of material that can be analyzed. The sample is placed into an ultra high vacuum (UHV) chamber and irradiated with x-rays which cause the ejection of photoelectrons from the sample surface. Since x-rays do not normally cause charging problems or beam damage, XPS is applicable to a wide range of samples including metals, polymers, catalysts, and fibers. AES uses a beam of high energy electrons as a surface probe. Following electronic rearrangements within excited atoms by this probe, Auger electrons characteristic of each element present are emitted from the sample. The main advantage of electron induced AES is that the electron beam can be focused down to a small diameter and localized analysis can be carried out. On the rastering of this beam synchronously with a video display using established scanning electron microscopy techniques, physical images and chemical distribution maps of the surface can be produced. Thus very small features, such as electronic circuit elements or corrosion pits in metals, can be investigated. Facilities are available on both XPS and AES instruments for depth-profiling of materials, using a beam of argon ions to sputter away consecutive layers of material to reveal sub-surface (and even semi-bulk) analyses.

AN ANALYSIS OF WAYS OF DETERMINING THE MATERIAL CONSTANTS FOR VISCOELASTIC MATERIALS [ANALIZA SPOSOBOW WYZNACZANIA STALYCH MATERIALOWYCH DLA MATERIALOW LEPKOSPREZYSTYCH]
Lech Dietrich and Karol Turski 1991 79 p In POLISH
(IFTR-28/91) Avail: CASI HC A05/MF A01

A complete solution of a fundamental equation under different initial conditions is derived for an elastoviscous material described by Burger's model. The possibilities for establishing the moduli of the materials for different sample loading schemes are defined. The experimental research results obtained for different loading methods and deformation rates for samples fabricated from an asphalt mixture are compared. It is established that the slip, cyclic deformation and loading at a constant deformation rate make it possible to determine the elasticity and viscosity moduli for different deformation rates while the results obtained from different loading methods make possible a uniform representation of the dependence of the moduli on the deformation rate. SENSITIVE DETECTION OF GAS-PHASE NITRO-CONTAINING ENERGETIC MATERIALS EMPLOYING 226-nm RADIATION Final Report, Feb. - Sep. 1992
Rosario C. Sausa, George W. Lemire, and Josef B. Simeonsson Jul. 1993 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267633; ARL-TR-157) Avail: CASI HC A03

The development of a novel technique for sensing trace vapors of -NO2 containing compounds is reported. This technique is based on the use of one laser operating at 226 nm to both photofragment the target molecule and detect the characteristic NO fragment, formed from a rapid predissociation of NO2 by resonance-enhanced multiphoton ionization (REMPI) and/or laser-induced fluorescence (LIF) via its A2 sum (+)(-X2Pi)(0,0) band origin. The analytical utility of this technique is demonstrated on a number of compounds, including dimethylnitramine, nitromethane, nitrobenzene, TNT, and RDX, employing molecular beam sampling with time-of-flight mass spectrometric analysis of the jet cooled analyte seeded in an atmosphere of buffer gas. With the present system, limits of detection of 8 and 24 parts-per-billion (ppb) are obtained for RDX and TNT, respectively, using approx. 100 microjoules pulse of laser energy. The limits of detection of the other compounds studied are also presented and discussed. DTIC

LONG DURATION EXPOSURE FACILITY EXPERIMENT m0003 DEINTEGRATION OBSERVATION DATABASE
S. R. Gyetvay, J. M. Coggi, and M. J. Meshishnek 17 Feb. 1993 200 p
(Contract F04701-88-C-0089)
(AD-A267579; TR-92(2935)-9; SMC-TR-93-38) Avail: CASI HC A09/MF A03

The four trays of the M0003 materials experiment on LDEF contained over 1600 samples from 20 subexperiments. The complete sample complement represented a broad range of materials including thin film optical coatings, paints, polymer sheets and tape, adhesives, and composites. The materials are intended for use in various spacecraft applications including thermal control, structures, optics, and solar power. Since some subexperiments included duplicate samples exposed on the leading and trailing edge trays for 9-week, 19-week, 40-week, and 69-month durations, comparisons provided a valuable time history of degradation. During the deintegration of the subexperiments from the M0003 trays, each sample was examined using bright field, dark field, and Nomarski light microscopy techniques. Over 3,000 color macrographs and photomicrographs were made of the condition of the M0003 trays and the individual samples. Records of the condition of the samples, photographic records, and all available references of publications on postflight analyses on each sample were collected in a computer database (4th Dimension(TM) for the Macintosh computer). Upon written request, the database records and photographs for specific samples may be obtained from The Aerospace Corporation Archives. Copies of the electronic database are available on floppy disk by request, as well. Directions for requesting the records, photographs, and database copies are given in this report. DTIC

ELECTRORHEOLOGICAL (ER) FLUIDS: A RESEARCH NEEDS ASSESSMENT
Irvin M. Krieger and Edward A. Collins May 1993 359 p

(Contract DE-AC04-91ER-30172)
(AD-A267588) Avail: CASI HC A16/MF A03

In 1947, Willis Winslow was awarded a U.S. patent on 'Methods and Means for Translating Electrical Impulse Into Mechanical Forces'. Winslow's patent makes use of an electrorheological (ER) fluid, i.e., one which is transformed from a liquid into a viscoelastic solid upon application of a strong electric field. Based on this gelation effect, a whole new technology has been proposed. This technology provides novel and efficient ways to control fluid flow and power transmission and to reduce energy loss and damage due to vibration and oscillation. A large number and variety of ER devices have been invented; they are described in publications and patents, and many exist as prototype and demonstration devices. ER devices such as shock absorbers, valves, transmissions, and fluid couplings are more energy-efficient than hydraulic, mechanical, or electromechanical devices which serve the same function. The power needed to operate an ER device is usually very low compared to the power controlled by the device, and its response can be almost instantaneous. DTIC

STRESS CORROSION CRACKING OF 316 SS AND INCOLOY-800 IN HIGH TEMPERATURE AQUEOUS CONTAINING SULFATE AND CHLORIDE
Weiguo Zhang, Fangliang Lin, Fengqin Gao, Hongyi Zhou, and Xiaoning Cao (Academia Sinica, Guiyang, China.) Mar. 1992 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-623325; CNIC-00598; IAE-0102) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The stress corrosion cracking (SCC) susceptibility of 316 stainless steel (SS) which was welded for primary pipe and Incoloy-800 (shot peening) for steam generator (SG) tube have been investigated by a slow strain rate test (SSRT) at a strain rate of 4.2 x 10(exp -6)/s. Tests were conducted at 315 C for 316 SS and 270 C for In-800 in the oxygenated simulated resin intrusion environment (acidic sulfate). Tests of the effect of combination of SO4(2-) and Cl(-) on SCC of Incoloy-800 were also carried out. The results indicate that Incoloy-800 is unsusceptible to SCC either in the environment with SO4(2-) (from a few ppm to 1000 ppm, pH approximately 3 to 4) or in the environment of combination of SO4(2-) (1000 ppm) and Cl(-) (from 2 to 1000 ppm). The 316 NG SS is susceptible to transgranular stress corrosion cracking (TGSCC) in the resin intrusion environment with SO4(2-) in high temperature water. DOE

LIFTED TURBULENT JET FLAMES Ph.D. Thesis
Jay A. Hammer 14 Apr. 1993 156 p
(Contract N00014-89-J-1991)
(AD-A267911) Avail: CASI HC A08/MF A02

Experiments were conducted on lifted, turbulent jet diffusion flames. A linear photodiode array was used to measure the temporal history of the liftoff height, h. Measurements of the mean liftoff height, bar-h, under a wide range of flow conditions, including several fuels, nozzle diameters, and exit velocities U(sub s), showed an approximately linear relationship between bar-h and U(sub s), with a slight dependence on Reynolds number. A strain-rate model was developed for liftoff, based on far-field scaling of turbulent jets; it provides an explanation for the linear dependence of bar-h on U(sub s). When the nozzle fluid was diluted with varying amounts of air it was found that the slope of the bar-h vs. U(sub s), line increases faster than predicted by the far-field scaling. The discrepancy is attributed to near-field effects. The amplitudes of the fluctuations in bar-h were found to be of the order of the local large scale of the jet but the time scales were found to be much larger than the local large-scale time of the turbulence tau(sub delta). By using fuels of different chemical times to vary tau(sub delta), the measured correlation time tau(sub 1/2) normalized by tau(sub delta) was found to collapse with Richardson number xi(sub h). SURFACE REACTIVITY OF COMBUSTION GENERATED SOOT PARTICLES Annual Technical Report, 1 Jun. 1992 - 30 May 1993
Robert J. Santoro 1 Jul. 1993 38 p
(Contract F49620-92-J-0314)
(AD-A268017; AFOSR-93-0601TR) Avail: CASI HC A03/MF A01

During the first year of this AASERT program, efforts have focused on the development of a sampling probe to extract soot particles from a laminar diffusion flame. Soot samples collected with this system are to be used to study the surface reactivity of the soot particles as a function of position in the flame. A suitable probe system has been developed and tested. Comparisons with laser-based measurements of percent conversion of fuel to soot show reasonable agreement. Additional studies have also been conducted to examine the applicability of laser-induced incandescence (LII) as a soot diagnostic. Results have demonstrated that the L2 technique compares very well with previous measurements in a well-studied ethene/air laminar diffusion flame. Measurements of soot volume fraction, particle diameter and number density have been demonstrated. DTIC

INVESTIGATIONS INTO THE RECOVERY OF WASTE SULFURIC ACID WITH CONCENTRATED SOLAR RADIATION Thesis - Tech. Hochschule, Aachen [UNTERSUCHUNGEN ZUR AUFBEREITUNG VON ABFALLSCHWEFELSAEUREN MIT KONZENTRIERTER SOLARER STRAHLUNG]
Oliver Weinmann 23 Mar. 1993 84 p In GERMAN
(Contract BMFT-0328823A)
(DLR-FB-93-11; ETN-93-94878) Avail: CASI HC A05/MF A01

For the recovery of waste sulfuric acid solarized processes are developed. The necessary process heat for the concentration and, if required, dissociation of the acid was supplied by concentrated solar radiation. An energy loss analysis of each facility components was carried out with a calculation of entropy flows, in order to show that highest losses appear in receivers. A simulation program was developed for the calculation of distillation column for the high concentration of sulfuric acid, considering

the real material behavior. In a test facility the positive effect of the concentrated solar radiation (represented by a solar simulator) on the decomposition of organic impurities of a waste sulfuric acid was demonstrated, compared to pure thermal oxidation. ESA

This paper reports on a collaborative effort to review the capabilities of several approaches to trace surface analysis. As a test case, Ni contamination of Si wafers in the dose range 10(sup 14) to 10(sup 10)/cm(sup 2) has been chosen. Emphasis of this paper is the capabilities of SARISA (surface analysis by resonant ionization of sputtered atoms), as an example of laser postionization secondary neutral mass spectrometry (SNMS), for detection of contaminants in the near-surface region. Results on analyses of the same standard samples by other techniques will also be presented. These techniques include total reflection x-ray fluorescence (TXRF) and heavy ion backscattering spectrometry (HIBS). Results of this comparison show that there are several techniques that can accurately determine metal contaminations on Si wafers in this concentration range and that the method of choice depends on other considerations such as speed or accuracy of analysis. CONTINUUM SOLVENT MODELS FOR COMPUTATIONAL CHEMISTRY
M. Colvin and C. Melius Jun. 1993 32 p
(Contract DE-AC04-76DR-00789)
(DE93-016329; SAND-93-8239) Avail: CASI HC A03/MF A01

This report describes an alternative to MD (molecular dynamics) and the empirical methods based on treating the solvent as a polarizable continuous medium (PCM). This model excludes many important properties of water such as explicit hydrogen bonding and size effects, but includes other properties of water that would otherwise only be accessible from computationally intensive MD. This report describes work supported by an LDRD grant, 'Computer-Designed Biomolecular Engineering,' to implement a polarizable continuum model of aqueous solvation for use with ab initio self-consistent field calculations. This implementation, based on methods developed by several research groups, uses accurate quantum chemical wavefunctions optimized with respect to the induced solvent charges. It is used to calculate several chemical properties tightly coupled to solvent interactions: proton transfer in water, the pKa's of alkyl amines, the energetics of aqueous phase glycine, and the protonation state of phosphoramide mustard. CHARACTERIZATION OF THE CYCLIC PLASTICITY OF POLYCRYSTALLINE ALUMINUM IN THE 90-300K DOMAIN: USE OF THE ULTRASONIC WAVE COUPLING TECHNIQUE - LOW FREQUENCY RESTRAINT Ph.D. Thesis [CARACTERISATION DE LA PLASTICITE CYCLIQUE DE L'ALUMINIUM POLYCRISTALLIN DANS LE DOMAINE 90-300K: UTILISATION DE LA TECHNIQUE DE COUPLAGE ONDE ULTRASONORE-CONTRAINTE BASSE FREQUENCE]
Franck Charvieux 1992 262 p In FRENCH
(ISAL-92-0083; ETN-93-94358) Avail: CASI HC A12/MF A03

The role of microstructure in the cyclic deformation of aluminum and the interactions between the microstructure and the dislocations which take part in the deformation are studied. The state of the art of centered face cubic metals during cyclic plastic deformation is assessed and ultrasonic methods of investigation are recalled. Models which describe the attenuation and the speed of propagation of an ultrasonic wave and show the use of the ultrasonic wave coupling technique-low frequency restraint on the characterization of the mobility of short and medium length dislocations are addressed. The methodology used to study the cyclic plasticity at different temperatures and the results obtained are presented. The results are discussed. ESA

Our objective was to develop a greatly improved understanding of the thermodynamic basis for processing and performance enhancement of Nb and Ta based alloys in order to provide better, scientifically-based support for current engineering efforts aimed at development of high temperature structural aerospace applications. A number of significant accomplishments have been made by the cooperating teams of researchers involved in this program. At the University of Florida, DeHoff and Brady have completed final modification of a computer program for calculating thermochemical diagrams of the type calculated by Dr. Pourbaix for high temperature oxidation. The development of such a program was one of the major milestones of the project. The program is ready for distribution upon request. DTIC

ARMY P/M RESEARCH AND DEVELOPMENT OVERVIEW Final Report
Robert J. Dowding, Martin G. Wells, and Andrew Crowson May 1993 23 p
(AD-A266921; ARL-TR-140) Avail: CASI HC A03/MF A01

The Army uses of powder metallurgy (P/M) extend from the conventional press and sinter to the more exotic processes of liquid phase sintering of tungsten heavy alloys (WHA) and powder injection molding (PIM). Many of the more advanced high performance applications require extensive research and development (R and D) prior to fielding of the application. Examples are the intense research into WHA in the last ten years. This research has led to great understanding of these heavy alloys and application into

some kinetic energy systems. The Navy has taken great advantage of WHA by employing them in the phalanx close-in weapon system (CIWS). The Army intends that research will lead to an alloy or composite of tungsten that, when used as a long rod penetrator, will perform as well as, or better than, current depleted uranium (DU) penetrators. This will allow possible replacement of the controversial DU. Powder injection molding of WHA is an area receiving attention because of the potential for producing small and medium caliber projectiles. The drawbacks at this time include the need to develop an alloy that does not require post sinter cold working to develop the strength required for these demanding applications. Other possible problems include producing slender long rod projectiles with desired product straightness. In addition to the work on tungsten alloys, a discussion is underway of other powder metallurgy R and D and is under active investigation within the Army. These topics include aluminum and titanium alloys, intermetallics, and ultrahigh strength steels for structural and propulsion applications, as well as nonequilibrium P/M produced structures. DTIC

REACTIONS OF CHEMILUMINESCENCE INDUCED BY SINGLET OXYGEN WITH METALS Ph.D. Thesis - Paris-Sud Univ. [REACTIONS DE CHIMILUMINESCENCE INDUITES PAR L'OXYGENE SINGULET SUR LES SURFACES METALLIQUES]

Jean Lamarre 1992 143 p In FRENCH

(ONERA-NT-1992-13; ETN-93-94413) Avail: CASI HC A07/MF A02

The mechanisms of the chemiluminescence induced by the reaction of singlet oxygen and chlorine with heated metals was studied. This emission was proposed as a possible candidate for a visible chemical laser. The visible and infrared emission from the flame obtained with copper are found to be identical to that obtained from CuCl2 excited by collision with singlet delta oxygen. The comparison between the spectroscopic data obtained from visible and infrared emissions of the singlet oxygen/Cl2/Cu flame and those obtained from gaseous CuCl2 by laser induced fluorescence and by absorption allow to assign the chemiluminescence to CuCl2. The spectroscopic study of the flame obtained with high purity metals confirm that CuCl2 is really the emitter with copper and other metals, the minute traces of copper being involved in the reaction scheme. The experimental failures to obtain a visible laser effect using a high power chemical singlet oxygen generator suggests that the singlet oxygen/chlorine/copper medium cannot be used to produce a chemical visible laser. The results of the spectroscopic study of CuCl2 vapor confirm that this molecule is unlikely to be involved in a visible chemically pumped laser. ESA

PREDICTION OF STABLE TEARING OF 2024-T3 ALUMINUM ALLOY USING THE CRACK-TIP OPENING ANGLE APPROACH

J. G. Bakuckas, Jr. and J. C. Newman, Jr. Sep. 1993 24 p

(RTOP 538-02-10-01)

(NASA-TM-109023; NAS 1.15:109023) Avail: CASI HC A03/MF A01

In this study, the crack-tip opening angle (CTOA) approach was incorporated into a damage growth finite element program, MADGIC (Micromechanics Analysis and Damage Growth in Composites), and was used to predict stable tearing in a middle-crack tension 2024-T3 aluminum alloy specimen. The MADGIC code is a displacement based finite element program implemented with an incremental elastic-plastic algorithm used to model elastic-plastic behavior and a nodal splitting and nodal force relaxation algorithm used to generate crack surfaces. Predictions of the applied stress as a function of crack extension and applied stress as a function of load-line displacement were in good agreement with experiments and with similar predictions made using an existing finite element program, ZIP2D. In addition, path integrals, namely, the J-integral and T*-integral, were also evaluated and compared with the CTOA approach. There appears to be a weak relationship between the CTOA and the T*-integral evaluated on a specific integration path during crack extension beyond maximum applied stress. This study further verifies that the CTOA can be used as an effective elastic-plastic fracture mechanics parameter to predict crack growth. Author

ENVIRONMENTAL EMBRITTLEMENT IN ORDERED INTERMETALLIC ALLOYS

C. T. Liu and N. S. Stoloff 1992 34 p Presented at the Minerals, Metals, and Materials Society/American Society for Metals Materials Week 1992, Chicago, IL, 2-5 Nov. 1992

(Contract DE-AC05-84OR-21400)

(DE93-015307; CONF-9211117-9) Avail: CASI HC A03/MF A01

Ordered intermetallics based on aluminides and silicides possess many promising properties for elevated-temperature applications; however, poor fracture resistance and limited fabricability restrict their use as engineering material. Recent studies have shown that environmental embrittlement is a major cause of low ductility and brittle fracture in many ordered intermetallic alloys. There are two types of environmental embrittlement observed in intermetallic alloys. One is hydrogen-induced embrittlement occurring at ambient temperatures in air. The other is oxygen-induced embrittlement in oxidizing atmospheres at elevated temperatures. In most cases, the embrittlements are due to a dynamic effect involving generation and penetration of embrittling agents (i.e., hydrogen or oxygen) during testing. Diffusion of embrittling agents plays a dominant role in fracture of these intermetallic alloys. This chapter summarizes recent progress in understanding and reducing environmental embrittlement in these alloys. DOE

THE CORROSION PROTECTION OF METALS BY ION VAPOR DEPOSITED ALUMINUM

M. D. Danford Oct. 1993 25 p Sponsored by NASA. Washington

(NASA-TM-108425; NAS 1.15:108425) Avail: CASI HC A03/MF A01

A study of the corrosion protection of substrate metals by ion vapor deposited aluminum (IVD Al) coats has been carried out. Corrosion protection by both anodized and unanodized IVD Al coats has been investigated. Base metals included in the study were 2219-T87 Al, 7075-T6 Al, Titanium-6 Al-4 Vanadium (Ti-6Al-4V), 4130 steel, D6AC steel, and 4340 steel. Results reveal that the anodized IVD Al coats provide excellent corrosion protection, but good protection is also achieved by IVD Al coats that have not been anodized. Author

RECENT ADVANCES IN ORDERED INTERMETALLICS

C. T. Liu 1992 17 p Presented at the High-Temperature Ordered Intermetallic Alloys V, Boston, MA, 30 Nov. - 3 Dec. 1992

(Contract DE-AC05-84OR-21400)

(DE93-015308; CONF-9211205-2) Avail: CASI HC A03/MF A01

This paper briefly summarizes recent advances in intermetallic research and development. Ordered intermetallics based on aluminides and silicides possess attractive properties for structural applications at elevated temperatures in hostile environments; however, brittle fracture and poor fracture resistance limit their use as engineering materials in many cases. In recent years, considerable efforts have been devoted to the study of the brittle fracture behavior of intermetallic alloys; as a result, both intrinsic and extrinsic factors governing brittle fracture have been identified. Recent advances in first-principles calculations and atomistic simulations further help us in understanding atomic bonding, dislocation configuration, and alloying effects in intermetallics. The basic understanding has led to the development of nickel, iron, and titanium aluminide alloys with improved mechanical and metallurgical properties for structural use. Industrial interest in ductile intermetallic alloys is high, and several examples of industrial involvement are mentioned. DOE

TERNARY ALLOYING EFFECTS IN POLYCRYSTALLINE (BETA)-NiAl

J. D. Cotton, R. D. Noebe (National Aeronautics and Space Administration. Lewis Research Center, Cleveland, OH.), and M. J. Kaufman (Florida Univ., Gainesville.) 1993 16 p Presented at the International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993

(Contract W-7405-eng-36)

(DE93-012675; LA-UR-93-1395; CONF-930997-1) Avail: CASI HC A03/MF A01

The purpose of this paper is to summarize alloying research to date in polycrystalline NiAl and its impact on microstructure and ambient temperature

properties. It is divided into the following sections: phase equilibria, solid solution effects and precipitation effects. Alloys that contain a high volume fraction of second phase (e.g. pseudobinary eutectic compositions) are not considered. Rather, the effects of dilute to moderate ternary alloying additions on the structure and properties of (beta)-NiAl are reviewed. It is already well established that stoichiometry is paramount in controlling mechanical properties of the binary compound. Since the addition of a third element is equally important, ternary phase equilibria are reviewed first. Solid solution strengthening is probably the least well understood particularly with respect to the nature of point defects and their contribution to strength. Characterization of these defects and their role in mechanical properties may well hold the key to future development of NiAl-based materials. With regard to second phases, there is limited evidence that the classical precipitation hardening mechanisms for metals are also applicable to NiAl. DOE

APPLICATION OF IN SITU SCANNING X RAY FLUORESCENCE TO STUDY THE CONCENTRATION OF METAL IONS IN SIMULATED PITS
H. S. Isaacs, A. J. Davenport, Cho Jeong-Hwan (Yonsei Univ., Seoul, Republic of Korea.), M. L. Rivers (Chicago Univ., IL), and S. R. Sutton (Chicago Univ., IL.) 1993 8 p Presented at the 12th International Corrosion Congress, Houston, TX, 19-24 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014054; BNL-48706; CONF-9309150-3) Avail: CASI HC A02/MF A01

X-ray energy-dispersive spectroscopy has been used to study the compositions of metal ions in solutions developed during localized corrosion. An electrochemical cell was designed to simulate a corrosion pit, maintaining one-dimensional diffusion and fulfilling the requirements for x-ray fluorescence measurements. The working electrode consisted of a dissolving thin foil of Type 304 stainless steel sealed between Mylar sheets through which the x-ray beam passed. Concentration gradients within the artificial pit were quantitatively determined. DOE

POTENTIAL TRANSIENTS, TRANSMISSION AND ELECTROCHEMICAL CORROSION DETECTION
H. S. Isaacs and Jeong-Hwan Cho (Yonsei Univ., Seoul, Republic of Korea.) 1993 7 p Presented at the 12th International Corrosion Congress, Houston, TX, 19-24 Sep. 1993
(Contract DE-AC02-76CH-00016)
(DE93-014055; BNL-48707; CONF-9309150-4) Avail: CASI HC A02/MF A01

The transmission of potential along a passive metal/electrolyte interface is important in open circuit corrosion monitoring when the containment system rather than an insulated metal specimen is monitored. Potential variations have been considered for transitory and sustained corrosion processes. The observed signals are modified and delayed by the passive surface. Using a transmission line as the equivalent circuit of a pipe and incorporating the impedance characteristics of the passive-metal/solution interface enabled a quantitative analysis of the effectiveness of corrosion monitoring methods to be carried out. DOE

MEASUREMENT AND ANALYSIS OF CRITICAL CTOA FOR AN ALUMINUM ALLOY SHEET
D. S. Dawicke (Analytical Services and Materials, Inc., Hampton, VA.), M. A. Sutton (South Carolina Univ., Columbia.), J. C. Newman, Jr., and C. A. Bigelow Sep. 1993 33 p
(RTOP 538-02-10-01)
(NASA-TM-109024; NAS 1.15:109024) Avail: CASI HC A03/MF A01

The stable tearing behavior of thin sheets of 2024-T3 aluminum alloy was investigated for middle crack tension, M(T), and compact tension, C(T), specimens. The surface crack-tip opening angle (CTOA), applied loads, crack extension, and local displacements were measured. A critical CTOA fracture criterion was incorporated into a two-dimensional, elastic plastic finite element code and used to simulate the experimental fracture behavior. The CTOA measurements and observations of the fracture surfaces have shown that large values for surface CTOA were observed for small crack extensions (less than the sheet thickness); substantial tunneling of the crack was associated with small crack extensions; crack tunneling in the M(T) specimen was less than that observed in the C(T) configuration; for larger crack extensions, the measured CTOA values were determined to be approximately 6 degrees for both the M(T) and C(T) configuration; and for larger crack extensions, crack tunneling remained constant. The two-dimensional finite element predictions of fracture behavior assumed a constant critical CTOA value of 6 degrees and accounted for local crack tip constraint with a plane strain core of elements ahead of the crack tip. The plane strain core extended 5 mm above the crack plane. The simulations were within +/- 4 percent of the maximum applied load for the C(T) tests within 2 percent for the M(T) tests. A SULFUR SEGREGATION STUDY OF PWA 1480, NiCrAl, AND NiAl ALLOYS
D. T. Jayne (Case Western Reserve Univ., Cleveland, OH.) and J. L. Smialek Mar. 1993 15 p Presented at the Second International Conference on Microscopy of Oxidation, Cambridge, England, 31 Mar. 1993; sponsored by the Inst. of Materials
(RTOP 505-63-5A)
(NASA-TM-106289; E-8001; NAS 1.15:106289) Avail: CASI HC A03/MF A01

Some nickel based superalloys show reduced oxidation resistance from the lack of an adherent oxide layer during high temperature cyclic oxidation. The segregation of sulfur to the oxide-metal interface is believed to effect oxide adhesion, since low sulfur alloys exhibit enhanced adhesion. X ray Photoelectron Spectroscopy (XPS) was combined with an in situ sample heater to measure sulfur segregation in NiCrAl, PWA 1480, and NiAl alloys. The polished samples with a 1.5 to 2.5 nm (native) oxide were heated from 650 to 1100 C with hold times up to 6 hr. The sulfur concentration was plotted as a function of temperature versus time at temperature. One NiCrAl sulfur study was performed on the same casting used by Browning to establish a base line between previous Auger Electron Spectroscopy (AES) results and the XPS results of this study. Sulfur surface segregation was similar for PWA 1480 and NiCrAl and reached a maximum of 30 at% at 800 to 850 C. Above 900 C the sulfur surface concentration decreased to about 3 at% at 1100 C. These results are contrasted to the minimal segregation observed for low sulfur hydrogen annealed materials which exhibit improved scale adhesion. Author (revised)

VACANCY CONDENSATION AS THE PRECURSOR TO PASSIVITY BREAKDOWN
D. D. Macdonald 1993 12 p Presented at the Fall Committee Week of the National Association of Corrosion Engineers, Houston, TX, 26 Sep. - 1 Oct. 1993
(Contract DE-FG02-91ER-45461)
(DE93-012925; DOE/ER-45461/10; CONF-930998-1) Avail: CASI HC A03/MF A01

This paper outlines the events that are envisaged to occur, according to the Point Defect Model (PDM), during 'chemically-induced' breakdown of the barrier layer on passivated metals and alloys in aqueous environments. The essential hypothesis of the model is that the local generation of cation vacancies at the barrier layer/environment interface, due to the autocatalytic adsorption of a damaging species such as chloride ion into the oxygen vacancy structure, leads to an enhanced flux of cation vacancies across the film. If the vacancies that arrive at the metal/film interface cannot be annihilated by cation ejection from the metal, the vacancies will condense leading to the local decohesion of the barrier layer from the metal. A combination of film dissolution at the barrier layer/environment interface and residual stresses in the oxide film leads to the physical rupture of the film, marking a passivity breakdown event. The PDM accounts for a variety of empirically-established relationships for the nucleation of pits, including the fact that the breakdown voltage (V(sub c)) and induction time (t(sub ind)) are distributed quantities; that V(sub c) = V(sub c)(sup o) - blog (a(sub Cl(-))), where b is greater than 2.303RT/F; and that log (t(sub ind))(alpha) 1/(Delta)V, where (Delta)V = V (applied voltage) - V(sub c). Also, the model has been extended to account for alloying effects and, indeed, new alloys are now being designed on the basis of rules that have been derived from the PDM. DOE

DYNAMICAL ISING MODEL SIMULATIONS OF NUCLEATION AND GROWTH IN COPPER-COBALT ALLOYS
A. Cerezo (Oxford Univ., England.), J. M. Hyde (Oxford Univ., England.), R. P. Setna (Oxford Univ., England.), G. D. W. Smith (Oxford Univ., England.), and M. K. Miller 1992 7 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015336; CONF-921101-132) Avail: CASI HC A02/MF A01

A simple dynamical Ising model on a fixed lattice with a single bond energy parameter has been used to simulate the kinetics of diffusion during solid-state phase transformations in binary metallic alloys. Results of these simulations are compared with direct real-space measurements of the atomic distributions of elements in alloys, obtained with the position-sensitive atom probe. Despite the simplicity of the model, there is good quantitative agreement between the development of microstructure in the simulation and the nucleation and growth of cobalt-rich precipitates in copper-cobalt alloys. DOE

THE EFFECT OF LONG-TERM AGING ON THE IMPACT PROPERTIES OF MODIFIED 9Cr-1Mo STEEL
D. J. Alexander, P. J. Maziasz, and C. R. Brinkman 1992 7 p Presented at the Fall Meeting of the Metallurgical Society and American Institute of Metallurgical and Petroleum Engineers, Chicago, IL, 1-5 Nov. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015453; CONF-921109-6) Avail: CASI HC A02/MF A01

The Charpy impact and room-temperature tensile properties of two heats of modified 9Cr-1Mo steel have been examined after aging at temperatures from 482 to 704 C for times up to 75,000 h. In general, aging at lower temperatures (482, 538, or 593 C) resulted in little change in the room-temperature tensile properties, but rapid increases in the transition temperature, with the greatest increase for an aging time of 25,000 h. The upper-shelf energy level decreased, reaching a minimum at 25,000 h, followed by recovery at 50,000-h aging. At higher aging temperatures (649 and 704 C) there was little change in the transition temperatures, but significant softening at room temperature, and large increases in the upper-shelf energy. DOE

D. J. Alexander, K. B. Alexander, M. K. Miller, and R. K. Nanstad 1992 8 p Presented at the Fall Meeting of the Metallurgical Society and American Institute of Metallurgical and Petroleum Engineers, Chicago, IL, 1-5 Nov. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015454; CONF-921109-7) Avail: CASI HC A02/MF A01

The effect of long-term aging at intermediate temperatures on the mechanical properties of stainless steel welds was studied. Three type 308 multipass shielded metal-arc welds with ferrite levels of 4, 8, and 12% were aged up to 20,000 h at 343 C. Tensile tests showed little effect of aging on either the yield or ultimate tensile strengths, but the impact toughness was significantly degraded. The extent of the degradation increased with increasing ferrite content and increasing aging time. Examination of the microstructure with transmission electron microscopy and atom probe field-ion microscopy revealed that the ferrite phase had undergone spinodal decomposition as a result of aging. In addition, G-phase particles were observed at dislocations, and finer G-phase particles were homogeneously distributed throughout the ferrite phase. The changes in the mechanical properties and the fractography are discussed in light of the observed changes in the microstructure. DOE

THE INFLUENCE OF THERMAL AGING ON THE MICROSTRUCTURE AND FATIGUE PROPERTIES OF MODIFIED 9Cr-1Mo STEEL
B. G. Gieseke, C. R. Brinkman, and P. J. Maziasz 1992 10 p Presented at the Microstructure and Mechanical Properties of Aging Materials, Detroit, MI, 2-5 Nov. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015489; CONF-9211110-2) Avail: CASI HC A02/MF A01

Results of elevated-temperature low cycle fatigue and creep-fatigue tests are reported for one heat of modified 9Cr-1Mo steel in the normalized and tempered condition, after pre-aging 50,000 h at 538 and 593 C, and after pre-aging for 75,000 h at 538 C. These data show that pre-aging reduces the low cycle fatigue and creep-fatigue lives in comparison to unaged material. The magnitude of these reductions are discussed along with the impact of pre-aging on the creep-fatigue damage diagrams. The effect of environment on creep-fatigue life of unaged modified 9Cr-1Mo steels is also addressed. Transmission electron microscopy explains changes in mechanical properties due to thermal aging. In the unaged alloy, TEM shows that dynamic recovery/recrystallization is occurring after significant strain-induced dislocation hardening around a stationary and stable array of as-tempered carbides during creep-fatigue. In contrast creep-fatigue testing of the pre-aged alloy produced a much coarser cellular subgrain structure and dislocation recovery without recrystallization. Aging causes as-tempered carbide dissolution and/or reprecipitation together with additional precipitation of Laves (Fe2Mo) phase, which removes some of the precipitate-strengthening effects, and depletes solid-solution hardening effects on the dislocation networks and subgrain boundary structures. DOE

EFFECTS OF ALLOYING AND TEMPERATURE ON THE HIGH-TEMPERATURE OXIDATION OF Cr-Cr2Nb
P. F. Tortorelli, J. H. DeVan, and L. J. Carson (Lincoln Univ., PA.) 1993 10 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-015800; CONF-9305135-4) Avail: CASI HC A02/MF A01

Effects of alloying additions and temperature on isothermal and cyclic oxidation resistance of Cr-Cr2Nb alloys were examined for air exposures. An isothermal exposure temperature of 1100C led to rapid reaction of binary Cr-12 at.% Nb as manifested a high oxidation rate and nonprotective behavior. Generally parabolic kinetics, complicated by some isothermal scale cracking, were observed at 900-1000C. Scale damage was exacerbated by thermal cycling. The addition of 8 at.% Al to Cr-12 at.% Nb did not effect cyclic oxidation resistance, but there was some evidence that scale adherence on Cr-6 at.% Nb-8 at.% Al was better than that for binary Cr-6 at.% Nb. Alloying additions of Al (up to 18 at.%) or Re (2 at.%) did not improve the isothermal oxidation resistance of Cr-12 at.% Nb. However, the tendency for scale damage during both isothermal and thermal cycling exposures suggests that alloying additions that specifically improve scale plasticity or modify growth stresses could be effective for Cr-Nb alloys. DEVELOPMENT AND COMMERCIALIZATION STATUS OF Fe3Al-BASED INTERMETALLIC ALLOYS
V. K. Sikka, S. Viswanathan, and C. G. McKamey 1993 9 p Presented at the International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015802; CONF-930997-3) Avail: CASI HC A02/MF A01

The Fe3Al-based intermetallic alloys offer unique benefits of excellent oxidation and sulfidation resistance, limited by poor room-temperature (RT) ductility and low high-temperature strength. Recent understanding of environmental effects on RT ductility of these alloys has led to progress toward taking commercial advantage of Fe3Al-based materials. Cause of low ductility appears to be related to hydrogen formed from reaction with moisture. The environmental effect has been reduced in these intermetallic alloys by two methods. The first deals with producing a more hydrogen-resistant microstructure through thermomechanical processing, and the second dealt with compositional modification. The alloys showing reduced environmental effect have been melted and processed by many different methods. Laboratory and commercial heats have been characterized. Tests have been conducted in both air and controlled environments to quantify environmental effects on these properties. These materials were also tested for aqueous corrosion and resistance to stress corrosion cracking. Oxidation and sulfidation data were generated and effects of minor alloying elements

on cyclic oxidation resistance were also investigated. Several applications have been identified for the newly developed iron aluminides. Commercialization status of these alloys is described. DOE

ENVIRONMENTAL EFFECTS ON IRON ALUMINIDES
J. H. DeVan and P. F. Tortorelli 1993 12 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-015820; CONF-9305135-5) Avail: CASI HC A03/MF A01

Corrosion properties of reference Fe3Al (28 at. % Al)-based compositions containing 2 and 5 at. % Cr were compared in a mixed gas composed of H2S-H2-H2O-Ar and in dehumidified air. The parabolic rate constant at 800C was a factor of 200 higher for the 5% Cr composition. Similar exposure of an alloy containing 16% Al and 5% Cr resulted in significantly higher weight gains than the Fe3Al-5% Cr composition. However all the alloys were significantly more resistant to the mixed gas than iron-based alloys with higher chromium and lower aluminum contents. The oxidation rates of the 2 and 5% Cr alloys were comparable in dry air at 800C and were a factor of two lower than the rate of the 2% Cr alloy in the mixed gas. An alloy of Fe with 16% Al, 5% Cr, and 0.1% Zr showed improved cyclic oxidation resistance in air at 900 and 1000C relative to binary alloys of 16 and 20% Al. The extent of oxidation of these 16% Al alloys was comparable to Zr-containing Fe3Al aluminides (28% Al) that develop adherent scales. DOE

THE EFFECT OF IRRADIATION ON THE MECHANICAL PROPERTIES OF 6061-T651 ALUMINUM
D. J. Alexander 1992 18 p Presented at the 16th Annual Symposium of American Society of Testing and Materials on Effects of Radiation on Materials, Denver, CO, 21-25 Jun. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015825; CONF-920673-19) Avail: CASI HC A03/MF A01

Critical components of the Advanced Neutron Source (ANS) reactor, to be built at Oak Ridge National Laboratory (ORNL), will be fabricated from 6061-T651 aluminum alloy. This alloy has been selected for its favorable neutronic, thermal, and mechanical properties. The effect of irradiation on the tensile properties and fracture toughness has been studied to allow the lifetime of these components to be estimated. Irradiations were carried out in the High Flux Isotope Reactor at ORNL at a temperature of approximately 95 C to a fluence of approximately 10(exp 26) m(exp -2) (thermal). Testing was conducted from room temperature to 150 C. The yield and ultimate tensile strengths were increased by irradiation, and the total elongation decreased, but the fracture toughness at 26 and 95 C was not degraded by irradiation and decreased only slightly at 150 C. ION IMPLANTATION EFFECTS ON SURFACE-MECHANICAL PROPERTIES OF METALS AND POLYMERS
G. R. Rao Apr. 1993 207 p
(Contract DE-AC05-84OR-21400)
(DE93-014661; ORNL/M-2711) Avail: CASI HC A10/MF A03

Fatigue of 8 complex alloys based on Fe-13Cr-15Ni-2Mo-2Mn-0.2Ti-0.8Si-0.06C, and single-crystal Fe-15Cr-15Ni, implanted with 400-keV B(sup +) and 550-keV N(sup +) (total dose 2.3 x (10 exp 16) ions/sq cm) was examined. 600 C creep was also examined. The dual implantation increased hardness but decreased fatigue life of the 8 complex alloys. An optimum strengthening level and a shift to grain boundary cracking were determined. The single crystals also showed reduced fatigue life after implantation. High temperature creep of E1 and B1 alloys were improved by the dual implantation. Four polymers (PE, polypropylene, polystyrene, polyethersulfone) were implanted with 200keV B(sup +) to 3 different doses. PS was also implanted with both B(sup +) and Ar(sup +). Near-surface hardness and tribological properties were measured. The hardness increased with dose and energy; wear also improved, with an optimum dose. DOE

METASTABLE PHASES IN MECHANICALLY ALLOYED ALUMINUM GERMANIUM POWDERS
P. J. Yvon and R. B. Schwarz 1993 21 p Presented at the 2nd Structural Applications of Mechanical Alloying Conference, Vancouver, Ontario, 20-22 Sep. 1993
(Contract W-7405-eng-36)
(DE93-008727; LA-UR-93-669; CONF-9309104-1) Avail: CASI HC A03/MF A01

Aluminum and germanium form a simple eutectic system with no stable intermetallic phase, and limited mutual solubility. We report the formation of a metastable rhombohedral gamma(sub 1) phase by mechanically alloying aluminum and germanium powders. This phase, which appears for compositions between 20 and 50 at.% germanium, has also been observed in rapidly quenched alloys, but there is disagreement as to its composition. By measuring the heat of crystallization as a function of composition, we determined the composition of the gamma(sub 1) phase to be Al70Ge30. We also produced Al70Ge30 by arc melting the pure elements, followed by splat-quenching at a cooling rate in the range of 10(exp 8) K/s. This method produced two metastable phases, one of which was found to be the gamma(sub 1) phase obtained by mechanical alloying. The other was a monoclinic phase reported earlier in the literature as gamma(sub 2). DOE

INVESTIGATION OF THE INFLUENCE OF APPLIED POTENTIAL ON EROSION-CORROSION OF COPPER IN ALKALINE CHLORIDE SOLUTIONS Final Report, 1 Dec. 1986 - 31 Mar. 1993
Mark E. Orazem May 1993 139 p
(Contract N00014-89-J-1619)
(AD-A266448) Avail: CASI HC A07/MF A02

A novel electrochemical cell incorporating a scanning ellipsometer was designed and used to investigate the hypothesis that the critical shear observed for the erosion-corrosion of copper was associated with a shear-induced removal of protective film. While high-shear flow was shown to increase the rate of corrosion of copper in aerated and de-aerated saline solutions, ellipsometry indicated that shear induced removal of protective films did not take place, even for shear stresses ten times the reported critical shear for erosion-corrosion of copper. Subsequent work showed that a differential mass transfer mechanism could generate localized corrosion, but the visual appearance of the surface did not resemble classical products of erosion-corrosion. Separate potentiodynamic and impedance experiments were conducted to identify the electrochemical behavior, and new techniques were developed to interpret impedance spectra. Papers resulting from this work are attached. DTIC

EVOLUTION OF MICROSTRUCTURE IN FACE CENTERED CUBIC METALS DURING IRRADIATION: A REVIEW
F. A. Garner Jun. 1993 45 p Presented at the 3rd Conference on the Evolution of Microstructure in Metals during Irradiation, Chalk River (Canada), 29 Sep. - 2 Oct. 1992
(Contract DE-AC06-76RL-01830)
(DE93-015682; PNL-SA-21234; CONF-920970-8) Avail: CASI HC A03/MF A01

When fcc metals and alloys are irradiated at elevated temperatures, they tend to evolve toward saturation microstructures that are independent of the starting state of the metal and the early details of irradiation history. This leads to property changes and rates of dimensional change that also

eventually become independent of the starting state. The evolution of microstructure in complex alloys, especially during the transient regime, is usually determined by the complex interaction of many microstructural and microchemical processes. The more complex the alloy, the more difficult it is to identify and define the separate influence of each participating mechanism. The use of irradiation studies conducted on simple metals or model alloys assists in understanding the behavior of alloys of engineering relevance. A review of such studies shows that a number of prevailing perceptions of radiation-induced microstructural evolution are not universally correct. DOE

THE EFFECT OF OXYGEN, GRAIN SIZE, AND STRAIN RATE ON THE MECHANICAL BEHAVIOR OF FORGED P/M TANTALUM
Christopher A. Michaluk (Cabot Corp., Boston, MA.), George T. Gray, III (Los Alamos National Lab., NM.), and Tapan Chatterjee (Picatinny Arsenal, Dover, NJ.) 1993 10 p Presented at the Powder Metallurgy in Aerospace, Defense, and Demanding Applications, San Diego, CA, 8-11 Feb. 1993
(Contract W-7405-eng-36)
(DE93-011251; LA-UR-93-712; CONF-9302111-1) Avail: CASI HC A02/MF A01 (US Sales Only)

The effect of oxygen, grain size, and strain rate on the quasistatic and dynamic mechanical properties of extruded, forged, and annealed P/M tantalum containing two different levels of oxygen is addressed. The high oxygen (250-400 ppM) P/M materials were characterized as having higher flow stress and greater work hardening than wrought high purity tantalum. Work hardening and relative strain rate sensitivity exponents of the P/M materials were found to be relatively independent of oxygen level and grain size and slightly dependent on strain rate. This behavior may be due to the existence of fine dispersion of tantalum oxide particles. The state of oxygen in the P/M forgings was investigated by TEM analysis. DOE

BULK AND DEFECT PROPERTIES OF ORDERED INTERMETALLICS: A FIRST-PRINCIPLES TOTAL-ENERGY INVESTIGATION
C. L. Fu, Y. Y. Ye, and M. H. Yoo 1992 12 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015492; CONF-921101-124) Avail: CASI HC A03/MF A01

First-principles quantum mechanical calculations based on local-density-functional theory have been used to investigate the fundamental factors that govern the deformation and fracture behavior of ordered intermetallic alloys. Unlike in Ni3Al, the calculated elastic constants and shear fault energies indicate that anomalous yield strength behavior is not likely to occur in Ni3Si. From the calculated Griffith strength and a phenomenological theory relating fracture toughness to ideal cleavage strength, Ni3Si is predicted to be ductile with respect to cleavage fracture. For TiAl, we find the absence of structural vacancies due to the strong Ti-Al bonding and similar atomic radii for Ti and Al. For NiAl, the defect structure is found to be dominated by two types of defects--monovacancies on the Ni sites and substitutional antisite defects on the Al sites. For FeAl, on the other hand, we find a more complex defect structure, which is closely related to the importance of electronic structure effect in FeAl. More importantly, we predict the strong tendency for vacancy clustering in FeAl due to the large binding energy found for divacancies. Effects of thermomechanical history on microhardness are discussed in terms of the calculated results. DOE

EFFECTS OF PROCESSING AND PROLONGED HIGH TEMPERATURE EXPOSURE ON THE MICROSTRUCTURE OF Nb-1Zr-C SHEET
Mehmet Uz (Lafayette Coll., Easton, PA.) and R. H. Titran Oct. 1993 12 p Prepared for the MRS 1993 Fall Meeting, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AI03-86SF-16310; RTOP 583-02-21)
(NASA-TM-106370; DOE/NASA/16310-20; E-8176; NAS 1.15:106370)
Avail: CASI HC A03/MF A01

High temperature stability of the microstructure of Nb-1Zr sheet containing 0.1 and 0.06 wt. percent C was studied as affected by processing and prolonged 1350 K exposure with and without applied stress. Sheets were fabricated by cold rolling bars that were single-, double-, or triple-extruded at 1900 K. Creep samples were double-annealed (1 h at 1755 K + 2 h at 1475 K) prior to testing at 1350 K and 10,000 - 34,500 h. The microstructures of the as-cast, extruded, rolled, DA, and crept samples were characterized using various metallographic and analytical methods. The precipitates were rather coarse Nb2C initially, but transformed to finer (less than or equal to 1 micron) carbides of (Zr, Nb)C with each subsequent high temperature process. The grain size, and the relative amount and morphology of (Zr, Nb)C were found to be affected by the number of extrusions and to some extent by C-content. However, the microstructures of all the crept samples were similar with (Zr, Nb)C distributed throughout the matrix indicating that prolonged exposure to 1350 K gave rise to complete transformation of Nb2C to (Zr, Nb)C regardless of the processing history. These and other observations are presented with the emphasis on the correlation between processing, microstructure, and creep properties. Author

CREEP DUCTILITY OF IRON AT VERY LOW STRAIN RATES: THE EFFECTS OF SULFUR
E. P. George, V. Sklenicka (Ceskoslovenska Akademie Ved, Brno.), and D. P. Pope (Pennsylvania Univ., Philadelphia.) 1992 6 p Presented at the Minerals, Metals, and Materials Society/American Society for Metals (TMS/ASM) Materials Week 1992, Chicago, IL, 2-5 Nov. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015490; CONF-9211117-8) Avail: CASI HC A02/MF A01

Creep ductility of iron containing sulfur (200, 20 and 1 wt ppm) was measured as a function of stress and temperature in constant-stress creep tests at 673, 773, 873, and 973 K in H(sub 2). Failure times ranged from one minute to one year. Creep strengths of the 20 and 1 ppm S material were similar, but the 200 ppm S material was stronger than the other two, especially at very low strain rates. Also, at a given strain rate, a ductility minimum is seen at 873 K, the depth of which increases with sulfur content and is the result of increased intergranular failure. The strain rate (or reciprocal of failure time) at which the failure mode changes from transgranular to intergranular fracture decreases with decreasing sulfur content. Intergranular creep cavities were found to nucleate on sulfides in the high-sulfur material, and on unidentified small particles -- presumably oxides -- in the other two. It is concluded that creep cavities nucleate easily on FeS particles but that nucleation on oxide particles is more difficult, especially when the interfacial sulfur content is low. However, it is

not possible to totally prevent cavity nucleation even after reducing the sulfur level to 1 ppm. DOE

SLIP, TWINNING AND TRANSFORMATION IN LAVES PHASES
S. M. Allen and J. D. Livingston 26 Jan. 1993 12 p
(Contract DE-FG02-90ER-45426)
(DE93-018164; DOE/ER-45426/2) Avail: CASI HC A03/MF A01

Research was concentrated on two-phase Ti-TiCr2 alloys, two-phase Fe-ZrFe2 alloys, and two-phase ternary Ni-Cu-Mg alloys containing MgNi2 and MgCu2 phases. Work demonstrated that a variety of room-temperature deformation processes are possible in Laves phases. A strain-induced phase transformation from C36 yields C15 structures is one mechanism for plastic deformation in ZrFe2. The C15 structure in TiCr2 deforms by slip and twinning. The microstructure after indentation of specimens containing C36 phases ZrFe2 and MgNi2 indicates that a variety of slip systems operate in this form. DOE

MEAN STRAIN EFFECTS ON THE STRAIN LIFE FATIGUE CURVE M.S. Thesis
Byron L. Smith 25 Mar. 1993 51 p
(AD-A267211) Avail: CASI HC A04/MF A01

Aluminum 7075-T6 was tested using a Fatigue Material Test System. After creating the monotonic and cyclic stress-strain curves to verify material properties, strain life test data were replicated twenty times each to obtain the statistical description of standard strain life curve for zero mean strain. The mean strain was then varied to create a total of four statistically described curves. Accounting for the statistical distribution, various characteristics were plotted in order to better understand the effects of mean strain. For example, strain range was plotted against the mean strain for given lives and results were compared to equations in use today that account for mean stress. DTIC

J-INTEGRAL AND HRR FIELD ASSOCIATED WITH STABLE CRACK GROWTH IN THIN ALUMINUM SEN SPECIMEN
G. B. May, F. X. Wang, and A. S. Kobayashi Jul. 1993 28 p
(Contract N00014-89-J-1276)
(AD-A267879; UWA/DME/TR-93/72) Avail: CASI HC A03/MF A01

Moire interferometry with line densities of 1200 and 40 lines per mm was used to determine the two orthogonal displacements surrounding a stationary and a stably extending crack, respectively in two thin 2024-T3 aluminum alloy, single-edge notched specimens. The displacement fields were used to compute the J-integrals for various contours during crack tip blunting and subsequent crack extension. As expected, the near-and far-field J-integral value prior to stable crack growth coincided with the LEFM strain energy release rate, G, and validated the experimental procedure. The far field J values increased with increasing stable crack grow-Lh but the crack tip J values within the nonlinear region remained constant. The HRR displacement field, which was computed from the experimentally determined far field J, agreed with the measured displacement field prior to stable crack growth and progressively deviated from the measured values with stable crack extension. STUDIES OF CHANGES IN THE ENERGY STORED IN METALS AS A RESULT OF SUBJECTING THEM TO A SURFACE TYPE TECHNOLOGICAL PROCESS [BADANIA ZMIAN ENERGII ZMAGAZYNOWANEJ W METALACH W WYNIKU PODDAWANIA ICH POWIERZCHNIOWYM ZABIEGOM TECHNOLOGICZNYM]
Stefan P. Gadaj 1991 99 p In POLISH
(IFTR-25/1991) Avail: CASI HC A05/MF A02

The possibility for estimating the effect of the original state of a material on energy accumulation under plastic deformation of metal is determined based on an analysis of the literature as well as theoretical and experimental studies. It is determined that research of this type has not yet proceeded beyond the initial phase. Research on the effect of an inhomogeneous initial state attributable to surface treatments on energy accumulation during distension of Austenite steel, carbon steel, and commercial grade pure titanium is analyzed. It is noted that surface treatments modify the course of this process only in the very initial distension domain. A mathematical description of the energy accumulation process and its dependence on energy conveyed to the metal under plastic deformation is proposed. Also given is a criterion for quantitative estimation of the effect of surface treatments on energy accumulation in the metal. Transl. by FLS

ANALYSIS OF THE STRENGTHENING OF ALUMINUM ALLOY UNDERGOING PLASTIC DEFORMATION UNDER CONDITIONS OF A COMPOUND STATE OF STRESS [ANALIZA WZMOCNIENIA STOPU ALUMINIUM ODKSZTALCONEGO PLASTYCZNIE W WARUNJKACH ZLOZONEGO STANU NAPREZENIA]
Ryszard Szczeboit 1991 94 p In POLISH
(IFTR-21/1991) Avail: CASI HC A05/MF A01

An experimental study relating to an analysis of conservation of a flow surface in a plane stressed state for material under additional reinforcement achieved by applying a load that imparts plasticity is discussed. Studies are carried out for different prestresses of the plasticity surface imposed on the side of such loading and on the opposite side of the load. Experiments were conducted to determine the contours of the complete plasticity surfaces that provided a basis for more comprehensive and extensive analysis of the conservation of such surfaces under extended preliminary strain of the test material. These results made it possible to determine the quantitative effect of material reinforcement on the change in surface dimensions and their position in the stress space and likewise served to test the theoretical principles underlying the reinforcement procedure. THE SPECIFIC HEAT OF TITANIUM DISILICIDE M.S. Thesis
William K. Sylla May 1993 73 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267543; AFIT/CI/CIA-93-094) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Titanium disilicide is a promising candidate for use in the circuitry of the next generation of micro-electronics. The fabrication techniques used

by the electronics industry require accurate thermodynamic data. We have therefore undertaken the measurement of the specific heat of TiSi2. The titanium disilicide alloy has been produced and characterized. The lattice parameters of TiSi2 have been found to be as follows: a = 8.2607 +/- 0.0004 A, b = 4.7967 +/- 0.0003 A, and c = 8.545 +/- 0.002 A by x-ray diffractometry. The specific heat of titanium disilicide has been measured from 100 K to 500 K by means of differential scanning calorimetry. These data show good agreement with accepted specific heat theory following the general shape of a Debye curve and approaching a Dulong-Petit value. From these data a Debye temperature of 510 +/- 80 K has been graphically approximated. The methodology of specific heat measurements using differential scanning calorimetry has been reviewed. DTIC

TRANSIENT PHENOMENA FOLLOWING PRECIPITATION AND RE-SOLUTION ANNEALS IN A NiTi ALLOY Final Report

L. V. Meisel and P. J. Cote May 1993 22 p

(AD-A267557; ARCCB-TR-93021) Avail: CASI HC A03/MF A01

Transient phenomena following anneals in a near stoichiometric NiTi alloy are investigated by means of differential scanning calorimetry (DSC). Precipitation anneals (350 C) raise the temperature range of the martensite and R-transformation. Subsequent cycling through the transformation range (-40 to 100 C) produces small changes in the martensite DSC peaks and no observable change in the R-peak. Subsequent re-solution anneals (600 C) produce dramatic effects: Ms rises approximately 20 C above its value preceding the precipitation anneal and the martensite DSC peak is very sharp and symmetric, while the R-transformation peak is not observable. During ensuing cycling, the martensite peak returns to its original form and position after about 300 cycles, and the R-peak appears after 4 cycles and is essentially invariant to cycling. The transient data are consistent with a dislocation model. DTIC

(IFTR-22/1992) Avail: CASI HC A03/MF A01

Energy accumulation in uniaxial distension along a group of austenite steel specimens with a low carbon concentration and different grain dimensions (80 micrometers, 8 micrometers) is investigated. The dislocation structure of coarse and fine grained steel with different selected deformation estimates is surveyed. An analysis of changes in its structure made possible an interpretation of the energy accumulation process bearing in mind the dislocation of the phenomenon as well as the estimate of the roll of grain and the boundaries of this process. The derived results were also analyzed from the viewpoint of the minimum free energy principle. Transl. by FLS

MICROMECHANISMS OF MONOTONIC AND CYCLIC SUBCRITICAL CRACK GROWTH IN ADVANCED HIGH MELTING POINT LOW-DUCTILITY INTERMETALLICS Final Report, 1 Apr. 1990 - 31 Mar. 1993

K. T. VenkateswaraRao, L. Murugesh, and R. O. Ritchie May 1993 120 p

(Grant AF-AFOSR-0167-90)

(AD-A267764; UCB/R/93/A1091) Avail: CASI HC A06/MF A02

The next generation of high-performance engines will require stiffer materials operating at higher stress levels and capable of with-standing significantly higher temperatures up to 1650 C and above. Prime candidates for such applications include ordered intermetallics, ceramics, and composites based on metal, intermetallic, and ceramic or carbon matrices. However, these materials are currently of limited use due to their low ductility and toughness properties; moreover, an understanding of their fatigue resistance is still essentially lacking. Accordingly, the present research was aimed at examining one class of these materials, namely ductile-phase toughened intermetallic alloys, with respect to the critical factors influencing crack-propagation resistance under monotonic and cyclic loading. The model systems studied included TiNb- and Nb-reinforced gamma-TiAl, Nb-reinforced Nb3Al, and Nb-reinforced MoSi2. DTIC

LOW-TEMPERATURE SINTERING AND PHASE CHANGES IN CHROMITE INTERCONNECT MATERIALS

L. A. Chick, T. R. Armstrong, D. E. McCready, G. W. Coffey, G. D. Maupin, and J. L. Bates May 1993 12 p Presented at the 3rd International Symposium on Solid Oxide Fuel Cells, Honolulu, HI, 16-21 May 1993

(Contract DE-AC06-76RL-01830)

(DE93-015676; PNL-SA-21622; CONF-9305100-1) Avail: CASI HC A03/MF A01

Sintering shrinkage curves and phase changes were compared for calcium-substituted lanthanum chromates with either slight Asite enrichment or depletion. Of the former type, La(0.7)Ca(0.31)CrO3 that was synthesized by the glycine-nitrate method sintered to high density in air at 1250 C, exhibiting two rapid-shrinkage events. Weight loss measurements corroborated XRD data showing that, prior to densification, over half the Ca resided in non-perovskite phases including CaCrO4. In the La(0.7)Ca(0.31)CrO3, densification was closely associated with re-dissolution of the Ca into the perovskite. DOE

ANISOTROPIC PHASE SEPARATION IN AMORPHOUS Fe-Ge ALLOYS

M. J. Regan and A. Bienenstock Apr. 1993 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993

(Contract DE-AC03-76SF-00515)

(DE93-015255; SU-SLAC-PUB-6139; SLAC/SSRL-0010; CONF-930405-17) Avail: CASI HC A02/MF A01

Magnetron sputtered amorphous Fe(x)Ge(100-x) films have been examined with anomalous small-angle x-ray scattering (ASAXS) in an attempt to characterize composition fluctuations which have been previously reported in this system. Films grown under various deposition conditions have been studied, with the scattering vector both in and oblique to the plane of the films, to search for anisotropy. By manipulating the deposited power flux and rates of growth, films which have the same composition can be grown to different states of phase separation. The total correlation functions have been calculated from the oblique scattering experiments. The anisotropy can be successfully modeled as a close-packing of oriented prolate ellipsoidal particles, with the elongated axis along the direction of film growth. A method for using these measurements to determine the compositions of the phase-separating species has been developed and utilized. The results indicate phase separation into a-Ge and a-FeGe2 for the a-Fe(x)Ge(100-x) (x less than 33) alloy. DOE

CHARACTERIZATION OF METALLIC MULTILAYERS USING X RAY DIFFRACTION ANALYSIS

Saad Mohamed Harb Alyan and Jharna Chaudhuri 1993 87 p
(NIAR-93-13) Avail: CASI HC A05/MF A01

Kinematic x-ray diffraction analysis models are employed to study metallic multilayer films, to gain insight into the quality of these films, and to characterize their composition and interplanar spacing wave profiles. Both gold/nickel superlattice and titanium/nickel superlattice modulated films are included in this investigation. All kinematic models employed provide an excellent means to evaluate the multilayering techniques and the quality of the modulated films. Results indicate the high structural and chemical orders of the multilayered superlattices studied. Coherent interfaces, however, are found to be dependent on the thickness of each material layer within one repeat period of the superlattice film. Author

THE EFFECT OF ELECTRIC DISCHARGE MACHINED NOTCHES ON THE FRACTURE TOUGHNESS OF SEVERAL STRUCTURAL ALLOYS Final Report

J. A. Joyce and R. E. Link Apr. 1993 84 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268605; CRDKNSWC-SSM-61-93-01; NUREG-CR-5981) Avail: CASI HC A05

Recent computational studies of the stress and strain fields at the tip of very sharp notches have shown that the stress and strain fields are very weakly dependent on the initial geometry of the notch once the notch has been blunted to a radius that is 6 to 10 times the initial root radius. It follows that if the fracture toughness of a material is sufficiently high so that fracture initiation does not occur in a specimen until the crack-tip opening displacement (CTOD) reaches a value from 6 to 10 times the size of the initial notch tip diameter, then the fracture toughness will be independent of whether a fatigue crack or a machined notch served as the initial crack. In this experimental program, the fracture toughness (Jlc and J resistance (J-R) curve, and CTOD) for several structural alloys was measured using specimens with conventional fatigue cracks and with EDM machined notches. The results of this program have shown, in fact, that most structural materials do not achieve initiation CTOD values on the order of 6 to 10 times the radius of even the smallest EDM notch tip presently achievable. TENSILE AND STRESS-RUPTURE BEHAVIOR OF HAFNIUM CARBIDE DISPERSED MOLYBDENUM AND TUNGSTEN BASE ALLOY WIRES Final Report

Hee Mann Yun (Cleveland State Univ., OH.) and Robert H. Titran Dec. 1993 12 p Proposed for presentation at the Materials Research Society Fall Meeting, Boston, MA, 1-5 Dec. 1993
(Contract DE-AI03-86SF-16310; RTOP 590-13-11)
(NASA-TM-106350; E-8128; NAS 1.15:106350; DOE/NASA/16310-18)
Avail: CASI HC A03/MF A01

The tensile strain rate sensitivity and the stress-rupture strength of Mo-base and W-base alloy wires, 380 microns in diameter, were determined over the temperature range from 1200 K to 1600 K. Three molybdenum alloy wires; Mo + 1.1w/o hafnium carbide (MoHfC), Mo + 25w/o W + 1.1w/o hafnium carbide (MoHfC+25W) and Mo + 45w/o W + 1.1w/o hafnium carbide (MoHfC+45W), and a W + 0.4w/o hafnium carbide (WHfC) tungsten alloy wire were evaluated. The tensile strength of all wires studied was found to have a positive strain rate sensitivity. The strain rate dependency increased with increasing temperature and is associated with grain broadening of the initial fibrous structures. The hafnium carbide dispersed W-base and Mo-base alloys have superior tensile and stress-rupture properties than those without HfC. On a density compensated basis the MoHfC wires exhibit superior tensile and stress-rupture strengths to the WHfC wires up to approximately 1400 K. Addition of tungsten in the Mo-alloy wires was found to increase the long-term stress rupture strength at temperatures above 1400 K. Theoretical calculations indicate that the strength and ductility advantage of the HfC dispersed alloy wires is due to the resistance to recrystallization imparted by the dispersoid. Author

PREPARATION OF HOMOGENEOUS ALUMINOSILICATE GELS BY SOL/GEL TECHNIQUES

M. Reese, J. Sanchez, and A. V. McCormick 12 Jul. 1993 9 p
(Contract N00014-91-J-1893)
(AD-A266823; TR-10-ONR) Avail: CASI HC A02/MF A01

The factors affecting the production of homogeneous aluminosilicate gels from alkoxide precursors were investigated. Aluminosilicate gels were made in acidic conditions with a prepolymerization of the silicate precursors followed by the addition of the alumina precursor. Confirming earlier studies, it was found that the gel homogeneity is increased when the rate of gelation decreases. The reduction of the water content and/or the aluminum precursor, and more surprisingly the increase of the acid concentratioh contributed to the gel time increase and thus the improvement of gel homogeneity. DTIC

MULTINUCLEAR NMR STUDY OF ALUMINOSILICATE SOL-GEL SYNTHESIS REASONS FOR THE HOMOGENEOUS GELATION USING THE PREHYDROLYSIS METHOD

G. A. Pozarnsky and A. V. McCormick 12 Jun. 1993 40 p
(Contract N00014-91-J-1893)
(AD-A266877; TR-1) Avail: CASI HC A03/MF A01

Aluminosilicate gels have been utilized in numerous optical, dielectric, and catalytic applications. These applications require a high degree of molecular homogeneity, but reproducible means of achieving this remain unobtainable for many compositions. In this work, reaction occurring in one of the most successful sol/gel processes are examined by means of both liquid and solid C-13, Si-29, 17, and Al NMR. The synthesis process studied was the method, optimized by Krol, of prehydrolyzing tetraethyl orthosilicate, TEOS,in ethanol, and subsequently adding aluminum sec-butoxide, and then further water. After prehydrolysis and addition of aluminum sec-butoxide, an aluminosilicate precursor is formed in which the aluminum is tetrahedrally coordinated to four silicate ligands. After adding further water, gelation is accompanied by the expansion of the tetrahedral aluminum to octahedral coordination; this apparently occurs by nucleophilic attack of silanol groups on the aluminum in the aluminosilicate precursor. At sufficiently low water to silicon molar ratios, where transparent gels and longer gel times result, this coordination expansion is preceded by condensation of the silicate ligands to form Si-O-Si. PREPARATION AND INVESTIGATION OF IMPROVED LOW VOLTAGE ELECTRON EXCITABLE PHOSPHORS Annual Technical Report, May 1992 - May 1993
S. S. Chadha, D. W. Smith, and A. Vecht May 1993 53 p
(Contract DAJA45-92-C-0007)
(AD-A266852; R/D-6812-EE-01) Avail: CASI HC A04/MF A01

Recent advances in the area of field emitting arrays point to the possibility of fabricating low voltage variants of the CRT. However, these advances also highlight the lack of suitable low voltage excitable phosphors. The aim of this contract is to remedy this situation and to provide suitable phosphors emitting RBG. The problem is being tackled by making either intrinsically or extrinsically conducting phosphors, the latter by the addition of suitably conducting fine particle powders. In addition, the evaluation of phosphors was possible by acquiring a low voltage demountable CRT system. Thus, far, the results from our experiments have been promising. A bright, pure green emitting phosphors (ZnGa2O4:Mn) and a red emitting phosphor (CaTiO2:Pr) were made. In-house prepared bluish-green emitting ZnO:Zn was shown to be as bright as the commercial ZnO:Zn phosphor. Photoluminescent thin film variants of both ZnO:Zn and ZnGa2O4:Mn were made using aerosol spray pyrolysis techniques. Therefore, we now have three low voltage phosphors instead of only on available at the start of this contract. Our aims are to optimize these phosphors further and to attempt other lattices. Small sealed devices will be made to simulate condition in real FED devices and phosphors will be supplied to any US FED manufacturer. DTIC

A STUDY OF RELAXATION TRANSITIONS IN THE POLYMERS UNDER THE INFLUENCE OF MAGNETIC FIELDS
B. Yu. Trifel and N. A. Abdullayev 15 Apr. 1993 8 p Transl. into ENGLISH from Azerbaydzhanskiy Khimicheskiy Zhurnal (USSR), no. 2, 1972 p 105-107
(AD-A263878; FASTC-ID(RS)T-0234-93) Avail: CASI HC A02/MF A01

As was mentioned in a previous work, the influence of a magnetostatic field on polymer materials results in a short-term, but considerable, increase in the dielectric power factor (tg delta). This results from the fact that during the relaxation of the polymer molecules, near the vitrification temperature (Tg) and under the influence of the magnetic field, more ordered structural formations are created. In order to determine the effect of the magnetic field on the physical structure of polymers, it was necessary to verify that during the measurement of tg delta in the magnetic field ferromagnetic impurities have no effect. The literature contains no information concerning the determination of ferromagnetic impurities (magnetic susceptibility) of polyvinyl chlorides. Analogous measurements were conducted only with inorganic simple compounds. The purpose of this work is to explain the presence of ferro- and paramagnetic impurities in the composition of previously investigated polyvinyl chloride samples. Author

SELF-DIFFUSION COEFFICIENTS OF SOL-GEL INTERMEDIATES
L. Ng and A. V. McCormick 12 Jul. 1993 28 p
(Contract N00014-91-J-1893)
(AD-A266957; TR-2) Avail: CASI HC A03/MF A01

Over the past few decades, the sol-gel technique has shown great potential for producing ceramic materials of designed composition and properties. A typical sol-gel process involves the hydrolysis and polymerization of one or more metal alkoxides in an alcohol solution in a batch reactor to form a homogeneous gel, which is then further treated to provide the type of ceramic desired (aerogel, glass, crystal, coating, etc.). Several authors have suggested that diffusion effects may influence the development of the gel microstructure. To investigate if diffusion effects are important, we begin by determining what governs the diffusivity of the precursors using the pulsed-gradient-spin-echo nuclear magnetic resonance (NMR) technique. This report focuses on the early stages of the batch reaction. The system chosen is the acid catalyzed hydrolysis and condensation of tetraethyl orthosilicate (TEOS) in ethanol. Our results from H-1 PGSE NMR and Si-29 NMR show that the diffusivities of the silicate precursors are not just a function of the molecular weight. Hydrogen bonding between the polar functional groups and the solvent also decreases the mobility of the reactants. Moreover, since hydrolysis increases and polymerization reduces the concentration of these polar groups, the mobility of the reactive oligomers changes in a complex manner. Combining our results from PGSE NMR and gas chromatography, we estimate the extent of hydrogen bonding effect on the mobility of various oligomers, providing a model to predict diffusivity trends throughout the batch reaction. INTRAMOLECULAR VERSUS INTERMOLECULAR CONDENSATION RATES IN THE ACIDIC POLYMERIZATION OF OCTAETHOXYTRISILOXANE
J. Sanchez and A. V. McCormick 12 Jul. 1993 17 p
(Contract N00014-91-J-1893)
(AD-A266982; TR-5) Avail: CASI HC A03/MF A01

Octaethoxy trisiloxane, (EtO)3Si- O-Si(OEt)2- O-Si(OEt)3, was synthesized and then polymerized in water/alcohol-solution in the presence of an acid catalyst. The reaction was monitored with Si-29 NMR. The rate constants of linear and cyclic condensation were estimated by curve-fitting and were compared. No evidence of depolymerization was found, indicating that condensation is irreversible in our conditions. In addition, it was found that the formation of trimeric cyclic species by ring closure is fast and competes effectively with chain extension condensation. These observations are consistent with previous suggestions, but in addition they provide a quantitative measure of selectivity that is much needed. Quantitative kinetic models for silicon alkoxide sol-gel processes need to account for cyclization at very early stages of the polymerization. DTIC

NMR AND THEORETICAL INVESTIGATION OF CATION BINDING WITH SOL-GEL SILICATES
J. Sanchez and A. V. McCormick 12 Jul. 1993 7 p
(Contract N00014-91-J-1893)
(AD-A266999; TR-3) Avail: CASI HC A02/MF A01

Previous reports suggest that the choice of base catalyst affects both the kinetics and structural evolution of SiO2 gelation from tetraethoxysilane (TEOS). Furthermore, these effects have been attributed to the interaction of the alkaline cations with charged silicate fragments. In this study, NMR analysis of alkali-metal nuclei and of Si-29 directly shows that during the condensation of silicon alkoxides in basic alcohol solutions, cations form

ion-pair complexes with negatively charged silicate groups. It is determined that the ion pair is formed most favorably with potassium. In seeking a predictive model of complex stability, we found it most successful to use a bond orbital electronegativity equalization model developed by Bergman and Hinze. DTIC

VERIFICATION OF A TWO-DIMENSIONAL INFILTRATION MODEL FOR THE RESIN TRANSFER MOLDING PROCESS Interim Report, Aug. 1990 - Aug. 1993

Vincent H. Hammond, Alfred C. Loos, H. Benson Dexter (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.), and Gregory H. Hasko (Lockheed Engineering and Sciences Co., Hampton, VA.) Aug. 1993 100 p

(Grant NAG1-343)

(NASA-CR-194597; NAS 1.26:194597; VPI-E-93-09; CCMS-93-15) Avail: CASI HC A05/MF A02

A two-dimensional finite element model for the infiltration of a dry textile preform by an injected resin was verified. The model, which is based on the finite element/control volume technique, determines the total infiltration time and the pressure increase at the mold inlet associated with the RTM process. Important input data for the model are the compaction and permeability behavior of the preform along with the kinetic and rheological behavior of the resin. The compaction behavior for several textile preforms was determined by experimental methods. A power law regression model was used to relate fiber volume fraction to the applied compaction pressure. Results showed a large increase in fiber volume fraction with the initial application of pressure. However, as the maximum fiber volume fraction was approached, the amount of compaction pressure required to decrease the porosity of the preform rapidly increased. Similarly, a power law regression model was used to relate permeability to the fiber volume fraction of the preform. Two methods were used to measure the permeability of the textile preform. The first, known as the steady state method, measures the permeability of a saturated preform under constant flow rate conditions. The second, denoted the advancing front method, determines the permeability of a dry preform to an infiltrating fluid. Water, corn oil, and an epoxy resin, Epon 815, were used to determine the effect of fluid type and viscosity on the steady state permeability behavior of the preform. Permeability values measured with the different fluids showed that fluid viscosity had no influence on the permeability behavior of 162 E-glass and TTI IM7/8HS preforms. Permeabilities measured from steady state and advancing front experiments for the warp direction of 162 E-glass fabric were similar. This behavior was noticed for tests conducted with corn oil and Epon 815. Comparable behavior was observed for the warp direction of the TTI IM7/8HS preform and corn oil. Mold filling and flow visualization experiments were performed to verify the analytical computer model. Frequency dependent electromagnetic sensors were used to monitor the resin flow front as a function of time. For the flow visualization tests, a video camera and high resolution tape recorder were used to record the experimental flow fronts. Comparisons between experimental and model predicted flow fronts agreed well for all tests. For the mold filling tests conducted at constant flow rate injection, the model was able to accurately predict the pressure increase at the mold inlet during the infiltration process. A kinetics model developed to predict the degree of cure as a function of time for the injected resin accurately calculated the increase in the degree of cure during the subsequent cure cycle. DESIGN, SYNTHESIS AND CHARACTERIZATION OF NOVEL NONLINEAR OPTICAL POLYMERS

Sukant Tripathy 31 May 1993 19 p

(Contract N00014-90-J-1148)

(AD-A267035) Avail: CASI HC A03/MF A01

The principal focus of the project is to develop new materials chemistry based on molecular level design and solid state chemistry. The goals have been to develop electroactive polymers with novel electronic, optical, and nonlinear optical properties. Second and third order nonlinear optical materials have been developed based on conjugated macromolecules and asymmetric anharmonic molecular electronic dipolar oscillators. In this multidisciplinary research effort, starting from first principles, polymeric systems have been developed with stable large nonlinear optical coefficients, ultrathin electroactive redox monolayers, molecular superlattices, etc. Sol-gel chemistry, photochemical crosslinking, and photopolymerization have been employed as engineering tools in materials fabrication and to elicit new phenomenon. THERMOCHEMISTRY OF SILICATE SPECIATION IN AQUEOUS SODIUM SILICATE SOLUTIONS: IONIZATION AND POLYMERIZATION OF SMALL SILICATE ION

J. Yang and A. V. McCormick 12 Jul. 1993 42 p

(Contract N00014-91-J-1893)

(AD-A266825; TR-8-ONR) Avail: CASI HC A03/MF A01

The thermochemistry of simple silicate oligomers in aqueous sodium silicate solutions is rationalized by a model that qualitatively predicts equilibria among monomer, dimer, and trimer silicate structures. Unlike previous models, it incorporates the influence of both silicate bonding and ion-solvent interactions on the stability of the anions. Although semiempirical molecular orbital calculations indicate that silicate bonds become less stable as charge increases, ion-solvent interactions tend to stabilize highly charged and compact silicate oligomers. Furthermore, polymerization is favored by the formation of highly stable water molecules and by a decrease of charge repulsion within the silicate structures. Although MNDO calculations indicate that the linear structures are more stable than the cyclic structures, ion-solvent interactions tend to stabilize the cyclic structures. Polymerization of compact silicate oligomers is also favored by producing more water molecules. Implications are summarized for larger silicate species. DTIC

ORGANIC POLYMERIC ELECTRO-OPTIC MATERIALS: SYNTHESIS, PROCESSING, AND DEVICE APPLICATIONS Final Report, Sep. 1988 - Dec. 1991

Jayant Kumar and Sukant Tripathy Apr. 1993 35 p

(Contract F19628-88-K-0048)

(AD-A267133; RL-TR-93-36) Avail: CASI HC A03/MF A01

A number of polymeric second and third order nonlinear optical materials were designed and synthesized. The materials were characterized for their thermal properties and processed into thin films by the Langmuir-Blodgett technique or spin coating methods which then were evaluated by second harmonic generation and electric field induced phase changes by interferometry. A stable second order nonlinear coefficient was obtained in crosslinked systems. Waveguiding with low loss was achieved in spin coated nonlinear optical polymer films, and frequency doubling experiments in waveguide configuration were performed. DTIC

ENGINEERING DESIGN OF SUB-MICRON TOPOGRAPHIES FOR SIMULTANEOUSLY ADHERENT AND REFLECTIVE METAL-POLYMER INTERFACES

Christopher A. Brown 29 Oct. 1993 56 p

(Grant NAG1-1476)

(NASA-CR-194573; NAS 1.26:194573) Avail: CASI HC A04/MF A01

The approach of the project is to base the design of multi-function, reflective topographies on the theory that topographically dependent phenomena react with surfaces and interfaces at certain scales. The first phase of the project emphasizes the development of methods for understanding the sizes of topographic features which influence reflectivity. Subsequent phases, if necessary, will address the scales of interaction for adhesion and manufacturing processes. A simulation of the interaction of electromagnetic radiation, or light, with a reflective surface is performed using specialized software. Reflectivity of the surface as a function of scale is evaluated and the results from the simulation are compared with reflectivity measurements made on multi-function, reflective surfaces. PHOTOCHEMISTRY IN THIN POLYMERIC FILMS Final Report, 15 Mar. 1990 - 14 Mar. 1993

Thomas J. Meyer and Richard W. Linton May 1993 7 p

(Contract DAAL03-90-G-0062)

(AD-A266716; ARO-27664.7-CH-SM) Avail: CASI HC A02/MF A01

A goal of the research funded by this grant was to exploit the known

photochemical and photophysical properties of (d-pi6) transition metal complexes for the preparation and utilization of novel microstructures in electroactive polymeric films. Thin polymeric films containing polypyridyl complexes of Fe(II), Ru(II), Os(II), and Zn(II) have been prepared on a variety of conducting substrates by well established electropolymerization techniques. A majority of the research involved films prepared by the reductive polymerization of vinyl substituted pyridyl ligands, such as 4-vinyl-4'methyl-2, 2'-bipyridine and 4-vinylpyridine. DTIC

PRODUCTION AND EVALUATION OF DENSE CERAMIC COMPOUNDS BY COMBUSTION SYNTHESIS AND DYNAMIC COMPACTION Final Report, 1 Oct. 1988 - 31 Aug. 1992

M. A. Meyers, J. C. LaSalvia, and D. Hoke 15 Apr. 1993 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contracts DAAL03-88-K-0194; DAAL03-90-G-0204)

(AD-A266742; ARO-28368.1-MS) Avail: CASI HC A02

The objectives of this research program were to apply combustion synthesis and dynamic forging in order to produce fully dense ceramics. The program was successfully carried out but was unfortunately terminated. TiC and TiB2 ceramics, TiC-Ni cermets, and Al2O3-TiB2 an TiB2-SiC ceramic-ceramic composites were successfully produced and characterized. The research effort yielded eleven technical publications, of which seven were (or will be) published in archival journals and four in conference proceedings. The work has been presented at eight technical meetings and has been very well received by the community. Three students were supported by this research program. Three M.S. degrees were awarded and two Ph.D. theses are in progress, with projected completion in Aug. 1992 and Jan. 1993. DTIC

OPTICAL AND INFRARED SPECTRA OF THERMALLY ANNEALED Pb IMPLANTED SiO2 GLASSES

D. O. Henderson (Fisk Univ., Nashville, TN.), S. H. Morgan (Fisk Univ., Nashville, TN.), R. Mu (Fisk Univ., Nashville, TN.), R. H. Magruder, III (Belmont Coll., Nashville, TN.), T. S. Anderson (Belmont Coll., Nashville, TN.), J. E. Wittig (Vanderbilt Univ., Nashville, TN.), and R. A. Zuhr 1992 9 p Presented at the 37th Annual Society of Photo-Optical Instrumentation Engineers International Symposium on Optical and Optoelectronic Applied Science and Engineering, San Diego, CA, 19-24 Jul. 1992

(Contract DE-AC05-84OR-21400)

(DE93-015304; CONF-920792-61) Avail: CASI HC A02/MF A01

Infrared reflectance between 4000 and 100 cm(exp -1) and optical spectra between 1.8 and 6.2 eV of high purity silica implanted with nominal doses of 1, 3, and 6 x 10(exp 16) Pb ions/sq cm were recorded before and after annealing at 400, 600, and 800 C for 1 hour. Curve resolution analysis of the Si-O stretching region resulted in six peaks which were characterized by their lineshape parameters. The oscillator strength of the ion induced defect peak at 1035 cm(exp -1) was found to depend on ion dose. The defect band at 1035 cm(exp -1) decreased to an intensity comparable to that of the unimplanted glass after thermal annealing for 1 hour at 800 C. Far infrared spectra indicated the formation of lead silicate particles after annealing. DOE

EFFECTS OF AGING TIME ON V205 SOL-GEL COATINGS

G. A. Pozarnsky, L. Wright, and A. V. McCormick 12 Jul. 1993 18 p

(Contract N00014-91-J-1893)

(AD-A266824; TR-6-ONR) Avail: CASI HC A03/MF A01

Vanadium pentoxide (V2O5) sols were used in conductive coatings and related applications. From cryo-Transmission Electron Microscopy (TEM) and Nuclear Magnetic Resonance (NMR) spectroscopic studies of the gelation, there are several intermediate structures and reactions in this process, but no information is yet available on the effects of aging on the dependent properties of viscosity, conductance, and film morphology in the coating process. The changes in these properties were observed over a 30 day period by means of rheological measurements and microscopic observation of the dried coatings obtained. The study found that the sol viscosity and ability to wet substrates is related to the initial decomposition of the precursors in solution and the start of the polymerization process. Distinct differences were observed in coating morphology as later aggregation and agglomeration processes occurred. DTIC

ASSESSMENT OF CHROMATE AND NON-CHROMATE CONVERSION COATINGS FOR Al ALLOYS USING ELECTROCHEMICAL IMPEDANCE SPECTROSCOPY Final Report

F. Chang, M. Levy, and R. Huie Jun. 1993 23 p

(AD-A267205; ARL-TR-142) Avail: CASI HC A03/MF A01

A study was conducted to evaluate whether a non-chromate conversion coating (Sanchem) for Al alloys (Al 2024 and 7075) could be a suitable replacement for the currently used chromate conversion coating (Alodine) without compromising corrosion resistance. Electrochemical impedance spectroscopy (EIS) and salt spray testing were employed to compare the corrosion behavior of coatings consisting of the following: (1) pretreatment only (Sanchem or Alodine); (2) pretreatment (Sanchem or Alodine) plus primer (epoxy polyamide or waterborne epoxy); and (3) pretreatment (Sanchem or Alodine) plus epoxy polyamide primer plus polyurethane topcoat. Results indicated that the experimental impedance values provided a reliable estimate of the film integrity and corrosion protective capability, that the Sanchem conversion coating generally compared favorably with the Alodine coating, and that higher impedance values attributed to the application of topcoat of both alloys which were treated with either Sanchem or Alodine and epoxy polyamide are characteristic of low conductivity, good barrier type coatings. However, additional tests are required before the Sanchem can be recommended as a reliable alternative to the Alodine coating. DTIC

STRUCTURES FROM LOW DIELECTRIC POLYIMIDES Patent Application

Anne K. St.Clair, inventor (to NASA), Terry L. St.Clair, inventor (to NASA), and William P. Winfree, inventor (to NASA) 28 Sep. 1992 31 p

(NASA-Case-LAR-14988-1; NAS 1.71:LAR-14988-1;

US-Patent-Appl-SN-954108) Avail: CASI HC A03/MF A01

A structure which is effective as an electrical insulator or as a transmitter-receiver of electromagnetic energy is prepared by providing a suitable substrate and covering the substrate with an adhering layer of a low dielectric, high temperature, linear aromatic polyimide. This polyimide is prepared by selecting aromatic diamine and aromatic dianhydride reactants to meet at least two of the following three conditions: a reactant must have minimal permanent or inducible electrical dipolar characteristics as a result of the presence of pendant or bridging groups therein, a reactant must impart a high degree of free volume to the polymer caused by inefficient chain packing therein in the solid state as a result of the presence of pendant or bridging groups therein, and a reactant must have fluorine atoms chemically attached thereto; and chemically combining equimolar quantities of the aromatic diamine and aromatic dianhydride reactants in a solvent to form a high molecular weight polyamic acid solution, and converting the high molecular weight polyamic acid to the corresponding low dielectric, high temperature linear aromatic polyimide. SYNTHESIS OF CERAMIC OXIDE POWDERS IN A MICROWAVE PLASMA DEVICE

D. Vollath and K. E. Sickafus 1993 11 p Presented at the 3rd European Ceramic Society Conference, Madrid, Spain, 13-17 Sep. 1993
(Contract W-7405-eng-36)
(DE93-012741; LA-UR-93-1518; CONF-930927-1) Avail: CASI HC A03/MF A01

Synthesizing oxide ceramic powders by application of a microwave plasma is of great advantage. The microwave plasma can be used two ways: to act as a source of heat for the pyrolysis of solutions and to excite gas phase reactions to obtain nanosized powders. Both applications are superior to standard methods. A microwave cavity well suited for these experiments and its operating characteristics are described. Using a microwave plasma as a source of heat for pyrolytic decomposition of nitrates in aqueous solutions leads to a fine grained product with particle sizes from 100 to 1000 nm. Crystallite sizes in those particles are in most cases less than 10 nm. This is demonstrated with zirconia-based ceramics, such as ZrO2 -- 3m% Y2O3 -- 20m% Al2O3. Depending on conditions during pyrolysis, it is possible to obtain a product in which alumina is either dissolved in zirconia or the onset of the phase separation is observed. Energy efficiency for this process is better than 80%. If the reactants are gaseous e.g., ZrCl4, it is possible to produce powders with mean crystallite sizes of about 4 nm. In the case of zirconia these particles are nanocrystalline with a cubic structure. This structure is not in equilibrium under the experimental conditions. DOE

THE EFFECT OF PROCESS PARAMETERS ON THE SURFACE FINISH OF PLASMA POLYMERS
S. A. Letts, R. C. Cook, P. Welch, R. McEachern, and E. Fearon Dec. 1992 11 p Presented at the American Chemical Society National Meeting, Denver, CO, 28 Mar. - 2 Apr. 1993
(Contract W-7405-eng-48)
(DE93-014112; UCRL-JC-112379; CONF-930304-22) Avail: CASI HC A03/MF A01

The surface finish of plasma polymers deposited in an inductively coupled discharge were measured as a function of gas flow rates. Surface finish was measured both optically and by AFM. The process parameters of the plasma polymerization were found to effect the surface finish. The gases used were trans-2-butene and hydrogen for hydrocarbon polymers. For bromocarbon polymers we added ethylbromide. The smoothest hydrocarbon polymer coatings had an RMS surface finish better than 1 nm. Bumps 200 nm high spaced approximately 1 micron apart grew on the surface of bromocarbon coatings when they were exposed to air. The composition of the bumps was found to be NH4Br by XRD and XPS analysis. We believe that nitrogen (from a small leak or desorption) dissociates in the discharge and reacts with hydrogen to form ammonia. The ammonia then reacts with HBr, a dissociation product of ethylbromide, to form NH4Br which is dispersed throughout the deposited layer. Humidity facilitates the transport of the NH4Br to the surface where it crystallizes. Bump growth was prevented by either dry storage or overcoating with 3 micron of hydrocarbon plasma polymer. Alternatively, the bumps could be washed from the surface with water. DOE

Non-brittle dielectric films are formed by blending a cyanoresin such as cyanoethyl, hydroxyethyl cellulose (CRE) with a compatible, more crystalline resin such as cellulose triacetate. The electrical breakdown strength of the blend is increased by orienting the films by uniaxial or biaxial stretching. Blends of high molecular weight CRE with high molecular weight cyanoethyl cellulose (CRC) provide films with high dielectric constants. NASA

SELECTIVE FORMATION OF POROUS SILICON Patent Application
Jones Fathauer, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 7 Jun. 1993 16 p
(Contract NAS7-918)
(NASA-Case-NPO-18735-1-CU; NAS 1.71:NPO-18735-1-CU; US-Patent-Appl-SN-073019) Avail: CASI HC A03/MF A01

A pattern of porous silicon is produced in the surface of a silicon substrate by forming a pattern of crystal defects in said surface, preferably by applying an ion milling beam through openings in a photoresist layer to the surface, and then exposing said surface to a stain etchant, such as HF:HNO3:H20. The defected crystal will preferentially etch to form a pattern of porous silicon. When the amorphous content of the porous silicon exceeds 70 percent, the porous silicon pattern emits visible light at room temperature. NASA

SWELLING EQUILIBRIA FOR TEMPERATURE-SENSITIVE AMPHOLYTIC HYDROGELS
J. P. Baker, D. R. Stephens, H. W. Blanch, and J. M. Prausnitz Sep. 1992 27 p
(Contract DE-AC03-76SF-00098)
(DE93-015264; LBL-32956) Avail: CASI HC A03/MF A01

Temperature-sensitive N-isopropylacrylamide (NIPA)-based ampholytic hydrogels were synthesized by copolymerizing NIPA with the cationic monomer methacrylamidopropyl trimethylammonium chloride (MAPTAC) and the anionic monomer sodium styrene sulfonate (SSS). The total nominal charge density of the hydrogels was held constant at 8 mol % (dry basis), while the molar ratio of anionic to cationic moieties within the hydrogels was varied. Swelling equilibria were measured in water at 6 C, and in aqueous sodium chloride solutions ranging in concentration from 10(exp -5) to 5 M and temperature ranging from 6 to 56 C. Consistent with expectations, the swelling behavior of the hydrogels was found to be controlled by temperature at low salt concentrations; as the sodium chloride concentration increased, temperature control of hydrogel swelling decreased. Slight antipolyelectrolyte behavior was observed for the hydrogel prepared with equal molar amounts of MAPTAC and SSS. DOE

RHEOLOGY AND MICROSTRUCTURE OF CONCENTRATED ZIRCONIA-ALUMINA SUSPENSIONS FOR GELCASTING COMPOSITES
A. Bleier and O. O. Omatete 1992 8 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015339; CONF-921101-133) Avail: CASI HC A02/MF A01

The relations among colloidal stability, suspension rheology, and solids loading are elucidated for zirconia-alumina mixtures containing 20 vol percent ZrO2, based on solids. The lower colloidal stability of ZrO2 limits the rheological properties of this system. If the zeta potential of ZrO2 is less than 49 mV, high degrees of pseudoplasticity, high yield stress, high viscosity, and long relaxation times characterize the binary suspensions. These effects occur, despite the fact that ZrO2 is the minor ceramic constituent. If the zeta potential of ZrO2 is maintained above 49 mV, suspensions with high solids loading (55 vol%) can be prepared which behave as Newtonian fluids over the 0-to-200 s(exp -1) shear rate range and as an elastic solid at higher rates. As the solids loading of a highly stable binary suspension is increased, the rheological properties change. They evolve from those of a near Newtonian-like fluid with nearly independent particles (40 vol%) to those of a pseudoplastic fluid with a weakly interacting particle network (50 vol%) to those of an elastic-like solid composed of crowded, strongly repulsive particles (55 vol%). Low-shear conditions for suspension-transport and mold-filling operations that ensure a homogeneous arrangement of ZrO2 and Al2O3 particles in a gelcast ceramic seem promising. DOE

THE INFLUENCE OF MICROSTRUCTURE ON THE MECHANICAL BEHAVIOR OF SILICON NITRIDE CERAMICS
P. F. Becher, H. T. Lin, S. L. Hwang, M. J. Hoffmann (Max-Planck-Inst. fuer Metallforschung, Stuttgart, Germany.), and I.-Wei Chen (Michigan Univ., Ann Arbor.) 1992 12 p Presented at the 16th Material Research Society International Symposium on the Scientific Basis for Nuclear Waste

Management Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015363; CONF-921101-131) Avail: CASI HC A03/MF A01

Elongated Si nitride grains produced during densification in a liquid phase can increase the fracture toughness, but this depends on the activation of intergranular rather than transgranular fracture. Bridging in the crack wake by elongated grains and pullout of some of these grains suggest that the crack wake mechanisms that contribute to toughening of whisker-reinforced ceramics can also operate in Si nitrides containing elongated grains. With diameters of the larger elongated grains approaching 9 microns, strengths greater than 800 MPa have been achieved along with Weibull moduli, but clustering of these larger elongated grains must be avoided. Fatigue of these toughened Si nitrides is influenced by silicate grain boundary phases. Design of toughened Si nitrides must consider effects of silicate phase composition and content on fatigue and creep. DOE

STRUCTURAL STUDIES OF SOL-GEL GLASSES Final Report, 15 Jul. 1989 - 14 Jul. 1992
Carole C. Perry 14 Jul. 1992 7 p
(Grant AF-AFOSR-0489-89)
(AD-A266277; AFOSR-93-0424TR) Avail: CASI HC A02/MF A01

Near and mid infrared spectroscopy and FT-Raman spectroscopy have been used to study silica/titania monoliths produced by the sol-gel route which have been subjected to selected heat treatments. Increasing thermal treatment temperature leads to a general strengthening of the gel-glass matrix although the incorporation of low levels (3% by weight) of titanium into tetrahedral sites only led to more disordered glasses than for silica alone. Evidence has been obtained for the formation of Si-O-Ti bonds principally during the later stages of densification at temperatures between 615 and 1000 C. The addition of titanium also leads to a reduction in surface 'free' silanol levels together with an increase in hydrogen bonded silanol levels and increasing amounts of water associated with the glass. The implication is that the incorporation of titanium onto the surface of the gel matrix leads to tighter binding of water molecules to silanol groups. DTIC

MODIFICATION OF FLUOROPOLYMER SURFACES WITH ELECTRONICALLY CONDUCTIVE POLYMERS Interim Report
Leon S. VanDyke, Charles J. Brumlik, Wenbin Liang, Junting Lei, and Charles R. Martin Jun. 1993 30 p
(Contract N00014-82-K-0612)
(AD-A266294; TR-86) Avail: CASI HC A03/MF A01

We describe methods for coating fluoropolymer surfaces with thin films of electronically conductive polymers. Modification of the fluoropolymer surface prior to coating with a conductive polymer is necessary to achieve good adhesion between the fluoropolymer membrane and the conductive polymer coating. We describe four different procedures for modifying the fluoropolymer surface so as to promote strong adhesion. These procedures are based on a wet chemical treatment of fluoropolymer or on exposure of fluoropolymer surface to a hydrogen plasma, an ultraviolet laser, or an electron beam. Finally, we show that it is possible to write patterns with the conductive polymer onto the fluoropolymer surface. DTIC

VUV THIN FILMS, CHAPTER 7
Muamer Zukic and Douglas G. Torr [1993] 121 p
(Grant NAGw-2898)
(NASA-CR-194634; NAS 1.26:194634) Avail: CASI HC A06/MF A02

The application of thin film technology to the vacuum ultraviolet (VUV) wavelength region from 120 nm to 230 nm has not been fully exploited in the past because of absorption effects which complicate the accurate determination of the optical functions of dielectric materials. The problem therefore reduces to that of determining the real and imaginary parts of a complex optical function, namely the frequency dependent refractive index n and extinction coefficient k. We discuss techniques for the inverse retrieval of n and k for dielectric materials at VUV wavelengths from measurements of their reflectance and transmittance. Suitable substrate and film materials are identified for application in the VUV. Such applications include coatings for the fabrication of narrow and broadband filters and beamsplitters. The availability of such devices open the VUV regime to high resolution photometry, interferometry and polarimetry both for space based and laboratory applications. This chapter deals with the optics of absorbing multilayers, the determination of the optical functions for several useful materials, and the design of VUV multilayer stacks as applied to the design of narrow and broadband reflection and transmission filters and beamsplitters. Experimental techniques are discussed briefly, and several examples of the optical functions derived for selected materials are presented. Author (revised)

PROPERTIES OF THIN FILMS FOR HIGH TEMPERATURE FLOW SENSORS Final Report, period ending 20 Aug. 1990
Sacharia Albin Jan. 1991 15 p
(Contract NAS1-18584; RTOP 505-61-01-05)
(NASA-CR-191526; NAS 1.26:191526) Avail: CASI HC A03/MF A01

Requirements of material parameters of high temperature flow sensors are identified. Refractory metal silicides offer high temperature sensitivity and high frequency response and are stable up to 1000 C. Intrinsic semiconductors of high band gap are also considered as sensor elements. SiC and diamond are identified. Combined with substrates of low thermal and electrical conductivity, such as quartz or Al2O3, these materials meet several requirements of high sensitivity and frequency response. Film deposition and patterning techniques suitable for these materials are identified. Author (revised)

Lagow (Exfluor Research Corp., Austin, TX.) May 1993 23 p Presented at the STLE Annual Meeting, Calgary, Alberta, 17-21 May 1993; sponsored by Society of Tribologists and Lubrication Engineers
(RTOP 505-63-5A)
(NASA-TM-106299; E-8038; NAS 1.15:106299) Avail: CASI HC A03/MF A01

A series of perfluoropolyalkylether (PFPAE) fluids was synthesized by direct fluorination. Viscosity-temperature properties, oxidation stabilities, oxidation-corrosion properties, bulk modulus, lubricity, surface tension and density were measured. It was shown that as the carbon to oxygen ratio in the polymer repeating unit decreases, the viscometric properties improve, the fluids may become poorer boundary lubricants, the bulk modulus increases, the surface tension increases and the fluid density increases. The presence of difluoromethylene oxide units in the polymer does not significantly lower the oxidation and oxidation-corrosion stabilities as long as the difluoromethylene oxide units are separated by other units. DETECTION OF SUBSURFACE DEFECTS IN MACHINED SILICON NITRIDE CERAMICS BY OPTICAL SCATTERING METHODS
W. A. Ellingson, D. M. Ayaz, M. P. Brada, and W. OConnell 1993 31 p Presented at the International Conference on Machining of Advanced Materials, Gaithersburg, MD, 20-22 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-015554; ANL/MCT/CP-79253; CONF-930793-1) Avail: CASI HC A03/MF A01

Si3N4 materials, from two manufacturers in the form of texture test bars, were studied by optical Fourier scattering methods. Subsurface defects were synthesized by either ultrasonically drilling or by grinding slots parallel to the surface. Because of unique optical transmission properties of ceramics subsurface defects, such as those likely to be caused by machining may be detected. S-polarized He-Ne laser light (lambda = 0.6328 microns) was used as the light source. Specular reflections were detected by an optical Fourier method which incorporated cross-polarization. Analysis of scattered laser light was accomplished using a CCD-array camera, an 8-bit A/D converter, and a PC with locally written software. Results show that subsurface defects can be detected and that for the surface finishes studied, changes in signal-to-noise (S/N) are observable. DOE

Major accomplishments of this program are the demonstrations summarized as follows: (1) Large grain (0.5 to 0.8 micrometer), high preferred orientation (100) films of Pt on SiO2/Si substrates by use of high deposition temperatures (600-650 C) with a trace of reactive O2 gas in the rf-PM sputtering gas. The Pt film, besides functioning as metallization for bottom electrodes for capacitors, promotes epitaxial like growth within its large grains and high crystal quality of the overlying KTN film. (2) Epitaxial growth of KTN films on GaAs (100) and 'r' plane' (1012) Sapphire substrates with film normal along (100) polar direction. (3) First time observation of Ferroelectric Curie-Weiss behavior of KTN films by rf-PM sputtering on GaAs and Pt/SiO2/Si substrates with peak dielectric constants of nearly 2250 (at 1 KHz); Sharp Curie transition temperatures (-9 to +3 C) with bulk single crystal like characteristics. (4) High optical transmittivity of KTN films on Sapphire with nearly 99.5% of theoretical transmittivity. (5) High quadratic EO effect in paraelectric phase of KTN films on GaAs and Si substrates. Observed EO response is nearly 70% larger than for substrates. Observed EO effect is nearly 70% larger than for the same effect in PLZT thin films in ferroelectric phase. DTIC

DETECTION AND DOSIMETRY OF CHEMICAL CONTAMINANTS IN POLYMERIC MATERIALS Final Report, 15 Sep. 1988 - 31 Mar. 1993
H. L. Frisch, W. M. Gibson, P. J. Toscano, and J. T. Welch 15 Jun. 1993 6 p
(Contract DAAL03-88-K-0198)
(AD-A266605; ARO-26072.25-CH-A) Avail: CASI HC A02/MF A01

New methods for the measurement of diffusion coefficients have been developed which enable the investigator to determine the local environment of a penetrant. The methods are general and facilitate discrimination between adsorbed and absorbed material. The diffusion coefficients of low molecular weight penetrants containing P-31 and F-19 can be readily measured in both glassy and rubbery polymers using solid state NMR probes that include cross-polarization, high powered H-1 decoupling and magic angle spinning. These measurements on fluorinated penetrants in both rubbery and glassy polymers have been confirmed by resonant nuclear reaction analysis using an alpha detection method of the product of F-19(p, ag)O-16 reaction at the strong 872 keV resonance. The resonant nuclear reaction techniques developed have the added feature that it is possible to investigate slowly - diffusing molecules whose study would be intractable by conventional methods. SOLID LUBRICANTS FOR SPACE STRUCTURES, PHASE 2 Final Report, 29 Jun. 1990 - 28 Jun. 1993
T. S. Sudarshan 14 Jun. 1993 97 p
(Contract DASG60-90-C-0114)
(AD-A266653) Avail: CASI HC A05/MF A02

In this Phase 2 effort, copper-lead alloys of three different compositions (90/10, 75/25, and 50/50 copper-lead) were processed by swirl die continuous casting in the form of ingots and further processed into powders using the gas atomization method. The powders were compacted using shock compaction and hot isostatic pressing. Friction and wear studies revealed that the 75/25 alloys had the best friction and wear rates under a range of sliding speeds and contact loads. Bearing cages, brushes, bushings and gears were produced from the different compositions and processing conditions. The components were tested in specially designed test rigs by the National Council for Tribology, U.K. The 90/10 hot isostatically pressed bearing cages outperformed the currently used lead-bronze cages and produced mini-noise for one (1) million revolutions. In the case of brushes, all the compositions and processing conditions outperformed all the materials that had been tested previously at NCT. Moderate to little improvements were observed in gears and bushings. DTIC

SPECTROSCOPIC INVESTIGATIONS OF NONAMBIENT SYSTEMS WITH MILLIMETER AND SUBMILLIMETER PROBES Final Report, 1 Oct. 1989 - 31 Dec. 1991
Frank C. DeLucia 20 Mar. 1993 20 p
(Contract DAAL03-89-K-0181)
(AD-A266537; ARO-27431.3-PH) Avail: CASI HC A03/MF A01

The project, 'Spectroscopic Investigations of nonambient systems with Millimeter and Submillimeter Probes,' addressed a broad range of scientific topics and technological developments important to this spectral region. For the purposes of this discussion, we have divided the report on research results into three parts: (1) Energy transfer in polyatomic molecules; (2) Molecular collisional processes at very low temperature (less than 5K); and (3) Development and uses of millimeter and submillimeter technology. Also included is a list of personnel who worked on these projects. DTIC

DEVELOPMENT OF A CONSTITUTIVE MODEL FOR CREEP AND LIFE PREDICTION OF ADVANCED SILICON NITRIDE CERAMICS
J. L. Ding (Washington State Univ., Pullman.), K. C. Liu, and C. R. Brinkman 1992 11 p Presented at the Annual Automotive Development Technology Contractors' Coordination Meeting, Dearborn, MI, 2-5 Nov. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015894; CONF-9211101-11) Avail: CASI HC A03/MF A01

A constitutive model capable of describing deformation and predicting rupture life was developed for high temperature ceramic materials under general thermal mechanical loading conditions. The model was developed based on the deformation and fracture behavior observed from a systematic experimental study on an advanced silicon nitride (Si3N4) ceramic material. Validity of the model was evaluated with reference to creep and creep rupture data obtained under constant and stepwise-varied loading conditions, including the effects of annealing on creep and creep rupture behavior. THE CERAMIC TECHNOLOGY PROJECT: TEN YEARS OF PROGRESS
D. R. Johnson and R. B. Schulz (Department of Energy, Washington, DC.) 1993 10 p Presented at the International Gas Turbine Institute (IGTI) Meeting, Cincinnati, OH, 24 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-015991; CONF-9305226-1) Avail: CASI HC A02/MF A01

The Ceramic Technology Project was initiated in 1983 for the purpose of developing highly reliable structural ceramics for applications in advanced heat engines, such as the automotive gas turbines and advanced heavy duty diesel engines. The reliability problem was determined to be a result of uncontrolled populations of processing flaws in the brittle, flaw-sensitive materials, along with microstructural features, such as grain boundary phases, that contribute to time dependent strength reduction in service at high temperatures. The approach taken to develop high reliability ceramics included the development of tougher materials with greater tolerance to microstructural flaws, the development of advanced processing technology to minimize the size and number of flaws, and the development of mechanical

testing methodology and the characterization of time dependent mechanical behavior, leading to a life prediction methodology for structural ceramics. DOE

PROCESSING OF COMPLEX SINTERED REACTION BONDED SILICON NITRIDE PARTS BY MICROWAVE HEATING
J. O. Kiggans, T. N. Tiegs, H. D. Kimrey, and C. E. Holcombe (Oak Ridge Y-12 Plant, TN.) 1993 9 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015811; CONF-930438-26) Avail: CASI HC A02/MF A01

Several studies have been conducted over the last several years assessing the use of microwave heating for processing reaction-bonded silicon nitride (RBSN) and sintered reaction-bonded silicon nitride (SRBSN). Although SRBSN test specimens up to 500g have been processed by using microwave heating, samples have been limited to simple shapes such as tiles. In this study, microwave packaging techniques were developed to process complex SRBSN parts and multiple samples within a single cycle. Physical and mechanical properties of test samples were measured. Comparison studies were performed using conventional furnace processing to establish baseline values and expected statistical variation. DOE

CHEMICAL VAPOR DEPOSITION OF Ta2O5 CORROSION RESISTANT COATINGS
D. W. Graham and D. P. Stinton 1992 13 p Presented at the 1992 Coatings for Advanced Heat Engines Workshop, Monterey, CA, 2 Aug. 1992
(Contract DE-AC05-84OR-21400)
(DE93-015488; CONF-9208207-2) Avail: CASI HC A03/MF A01

Silicon carbide and silicon nitride heat engine components are susceptible to hot corrosion by molten Na2SO4 which forms from impurities present in fuel and the environment. Chemically vapor deposited Ta2O5 coatings are being developed as a means to protect components from reaction with these salts and preserve their structural properties. Investigations to optimize the structure of the coating have revealed that the deposition conditions dramatically affect the coating morphology. Coatings deposited at high temperatures are typically columnar in structure; high concentrations of the reactant gases produce oxide powders on the substrate surface. Ta2O5 deposited at low temperatures consists of grains that are finer and have significantly less porosity than that formed at high temperatures. Samples of coatings which have been produced by CVD have successfully completed preliminary testing for resistance to corrosion by Na2SO4. DOE

INTERPENETRATING POLYMER NETWORK ACOUSTIC DAMPING MATERIAL Patent
Usman A. Sorathia, inventor (to Navy), William L. Yeager, inventor (to Navy), and Timothy L. Dapp, inventor (to Navy) 6 Jul. 1993 5 p Filed 28 Aug. 1991
(AD-D015889; US-Patent-5,225,498; US-Patent-Appl-SN-750992) Avail: US Patent and Trademark Office

Improved acoustic damping materials comprise interpenetrating polymer networks having a soft polymer component and a hard polymer component. The soft polymer component, constituting from 50 to 90, preferably 70, percent by weight of the material, is made by polymerizing an aromatic diisocyanate with a polyalkylene ether glycol, and the hard polymer component is a vinyl ester polymer made by polymerization of a vinyl ester resin such as the acrylate or methacrylate ester of the diglycidyl ether of a polyphenol. Optionally, the vinyl ester resin may be brominated, whereby increased fire retardance is conferred upon the interpenetrating polymer network. The mixture is cured at room temperature. DTIC

SUPERCONDUCTING CERAMICS: SELECTED PROPERTIES AND METHODS OF PRODUCTION [NADPRZEWODNIKI CERAMICZNE WYBRANE WLASNOSCI I METODY WYTWARZANIA]
Jerzy Ranachowski, Zdzislaw Librant, and Jerzy Raabe (Technical Univ. of Warsaw, Poland.) 1991 34 p In POLISH
(IFTR-23/1991) Avail: CASI HC A03/MF A01

The topic 'Analysis of Acoustic Features of Selected High-Temperature Ceramic Superconductors' was discussed under Program 02.03 between 1986 and 1990. Within the framework of this Program it has become necessary to fabricate corresponding samples for ultrasonic volume wave, resonant and surface wave analyses. It has become necessary to fabricate samples of different sizes using different technologies. Structural studies of the fabricated specimens were an important task; such studies encompassed measurements of the elasticity moduli, the average grain distribution, porosity measurements as well as the contents of different crystallization phases. Primary attention has been devoted to aging of the samples and losses of superconductivity. This issue is of special significance for samples with a deposited superconductivity thin layer. A SIMPLE CHEMICAL PROCEDURE FOR EXTENDING THE CONDUCTIVE STATE OF POLYPYRROLE TO MORE NEGATIVE POTENTIALS Interim Report
Leon S. VanDyke, Susumu Kuwabata, and Charles R. Martin Jun. 1993 35 p
(Contract N00014-82-K-0612)
(AD-A266235; TR-85) Avail: CASI HC A03/MF A01

The electronically conductive polymer polypyrrole is an electronic conductor at potentials positive of ca. -0.4 V vs. the saturated calomel electrode (SCE) and an electronic insulator at potentials negative of this value. As a result of this potential-dependent conductor/insulator transition, a polypyrrole film can be used as an electrode for redox couples with E(o)'s positive of ca. -0.4 V vs. SCE but cannot be used as an electrode for couples with E(o)'s negative of this value. We have discovered a simple chemical procedure that extends the conductive state of polypyrrole to ca. -1.1 V vs. SCE. This procedure entails treating the polypyrrole film with aqueous sodium hydroxide. We demonstrate this extension of the conductive state to more negative potentials in this paper. We also propose, and test, a chemical model that explains the extension of the conductive state. DTIC

MATERIALS PROCESSING AND MANUFACTURING TECHNOLOGIES FOR DIAMOND SUBSTRATE MULTICHIP MODULES (DSMCM)
David S. Dandy 1 Jul. 1993 6 p
(Contract N00014-93-1-2002)
(AD-A267316) Avail: CASI HC A02/MF A01

A detailed surface kinetics mechanism has been developed for the deposition of CH3, C2H2, and C onto a reconstructed (100) diamond surface. The mechanism accounts for the growth of alternating dimer-trough rows. The thermophysical properties of all structures present in the mechanism have been computed using the molecular mechanics program MM3(92). A diamond growth mechanism on the unreconstructed (100) surface has been used in a stagnation flow model to examine the effect of hydrocarbon injector location and inlet temperature on gas-phase species distributions and diamond growth rate in a DC arcjet reactor system typical of that in use at the Norton Company. It is predicted that there is an optimal injector location, dictated by operating conditions, that results in

maximum concentrations of reactive growth species CH(x) and consequently, in maximum diamond growth rate. DTIC

PHOTODEGRADATION OF POLYIMIDES. V1: EFFECT OF DONOR-ACCEPTOR GROUPS ON THE PHOTOOXIDATIVE STABILITY OF POLYIMIDES AND MODEL COMPOUNDS Technical Report No. 19
C. E. Hoyle, D. Creed, P. Subramanian, R. Nagarajan, and C. Pandey 13 Jul. 1993 36 p
(Contract N00014-91-J-1028)
(AD-A267319) Avail: CASI HC A03/MF A01

The photophysics of polyimides and several N-arylphthalimide model compounds has been investigated as part of an effort to understand the factors that control the oxidative photodegradation of these materials. Substituents that increase the donor-acceptor (D-A) character of both polymers and models cause an enhancement of the red-shifted electronic absorption and a shift to lower energy of the broad, weak fluorescence of these materials. Increasing solvent polarity causes a similar effect on the absorption and fluorescence spectra of the model compounds. Fluorescence quantum yields decrease with increasing D-A character in the series of model compounds and with increasing solvent polarity for a given compound. The triplet states of both polymers and models have been characterized in solution by laser flash photolysis, and intersystem crossing quantum yields have been determined. The triplet yields also decrease with increasing D-A character of the chromophore and with increasing solvent polarity. A comparison of fluorescence and phosphorescence spectra reveals a very small singlet-triplet energy gap. It seems likely that the lowering, by increased D-A character, of the yields of the triplet states that are intermediates in the photooxidative degradation, enhances the photostability of aromatic based polymides. DTIC

THE PHOTOCHEMISTRY OF POLY(METHYLPHENYLPHOSPHAZENE) Technical Report No. 20
C. E. Hoyle, D. Creed, P. Subramanian, I. B. Rufus, and P. Chatterton 13 Jul. 1993 26 p
(Contract N00014-89-J-1028)
(AD-A267320) Avail: CASI HC A03/MF A01

The photochemical reactions of poly(methylphenyl-phosphazene) (PMPP), a disubstituted poly(phosphazene), have been studied. UV-Irradiation results in chain scission in air-saturated dichloromethane solution, whereas in the absence of molecular oxygen, a bimolecular process, leading to extensive crosslinking and gel formation, predominates. The degradation of PMPP is not inhibited by quenchers of the triplet state. The reactions of PMPP most likely originate from the singlet state. Biphenyl has been identified as a major photoproduct from PMPP both in the presence and absence of molecular oxygen. DTIC

THE PHOTOPHYSICS OF POLY(METHYLPHENYLPHOSPHAZENE) Annual Report, 1 May 1992 - 30 Apr. 1993
C. E. Hoyle, D. Creed, P. Subramanian, I. B. Rufus, and P. Chatterton 13 Jul. 1993 27 p
(Contract N00014-91-J-1028)
(AD-A267321) Avail: CASI HC A03/MF A01

The photophysical properties of poly(alkylarylphosphazenes), particularly poly(methylphenylphosphazene). PMPP, with a methyl and a phenyl group on the phosphazene phosphorous atom, have been investigated using absorption and emission spectroscopy, as well as laser flash photolysis. The fluorescence spectrum of PMPP shows a red-shifted emission (decay time greater than 1 nanosecond) with a maximum at 430 nm when excited at 270 nm in solvents of varying polarity. The absence of a strong solvent effect on the position and the structure of the fluorescence spectrum suggests that the emission is not due to a charge-transfer state, but originates from a significant geometry shift in the excited state. The triplet state of PMPP was identified by laser flash photolysis. The phosphorescence spectrum of PMPP indicates a triplet energy of 79 kcal/mol. DTIC

INVESTIGATION OF THE EFFECTS OF POLYELECTROLYTE COATINGS ON COLLOID TRANSPORT IN POROUS MEDIA
T. M. Olson 1993 8 p
(Contract DE-FG03-89ER-60849)
(DE93-018300; DOE/ER-60849/T1) Avail: CASI HC A02/MF A01

The goal is to study the repulsive interaction forces between humic-coated colloids and negatively charged porous media surfaces. Filtration experiments were carried out on hematite coated with humic acid or NOM, in porous media or packed bed (silica bed). Effects of Ca(2+) are being studied. Results so far indicate that many humic coating properties (molecular size, acidity, polarity, and surface conformation) have an important effect on colloid attachment rates but very little effect on colloid electrophoretic mobility; steric repulsive forces are proposed to account for these observations. Some humic coatings are more effective in enhancing colloid transport in quartz beds than in enhancing colloid stability. Other effects are discussed. DOE

ELECTRICAL CONDUCTIVITY OF ION IMPLANTED LADDER AND SEMI-LADDER POLYMERS Final Report, 1 Nov. 1991 - 31 Dec. 1992
Arthur J. Epstein 2 Jul. 1993 58 p
(Contract F49620-92-C-0002)
(AD-A267432; AFOSR-93-0567TR) Avail: CASI HC A04/MF A01

Aromatic heterocyclic ordered rigid rod, ladder and semi-ladder polymers (including BBL, PBO, PBT, and BBB) combine exceptional high temperature stability with excellent mechanical properties as well as environmental stability. We have continued our systematic study of the electronic, photonic, and environmental properties of the pristine polymer. We have discovered the presence of a significant photoconductivity in PBO and characterized its photoluminescence. Extending our photoinduced absorption spectroscopy studies to the millisecond regime we have found the presence of two weak photoinduced optical absorptions. The difference in behavior as compared to other conjugated polymers likely reflects the increased order in the pristine rigid rod and ladder polymers. We have extended our temperature dependent charge transport (dc conductivity, microwave frequency conductivity and dielectric constant, thermoelectric power, magnetoconductivity, and electron spin resonance) studies of the ion implanted polymers as a function of implantation dosage. A nonmetal-to-metal transition is found as a function of increasing dosage

(occurring at 4 x 10(exp 16) ions/sq cm). For implanted samples of metallic behavior, a unique transition to a nonmetallic behavior has been discovered at 30 K. The origin of this transition is attributed to the opening up of a Coulomb gap. DTIC

TRANSFORMATION TOUGHENING OF COMPOSITE CERAMICS Final Report, 1 Mar. 1989 - 30 Sep. 1992

Waltraud M. Kriven 31 Dec. 1992 267 p

(Grant AF-AFOSR-0300-89)

(AD-A267304; UILU-ENG-93-5100; AFOSR-93-0482TR) Avail: CASI HC A12/MF A03

A systematic investigation into some possible transformation toughening alternatives to zirconia (ZrO2) has been conducted. Three systems have been focussed upon: dicalcium silicate (Ca2S104), dysprosia (DY203), and nickel sulfide (NiS). Composites of Ca2SiO4 in calcium zirconate (CaZrO3) or magnesia (MgO) or fine grained, single phase pure, and Ba-doped Ca2SiO4 were fabricated, microstructurally characterized, and mechanically evaluated. Although surface grinding was able to stress-induce the transformation in Ca2SiO4, a crack tip propagating in the bulk was not. A comprehensive crystallographic study of the transformation mechanisms implied that compressive shear, rather than tensile stresses were required. The mechanism could not controllably be nucleated by a propagating crack. Spontaneous thermal transformation of Ca2SiO4 was too powerful for a confining matrix and tended to cause dusting. The kinetics and mechanism of the transformation in single phase DY2O3 were studied and revealed that it only operated above 600 C. No transformation toughening in HIPPED SiC-DY2O3 composites could be detected at room temperature. Microstructural studies of industrial NiS in glass composites found a correlation between transformed NiS and deleterious fracture. DTIC

AN INVESTIGATION OF THE HYDROLYTIC RESISTANCE OF SODIUM-CALCIUM PLATE GLASS WITH A LAYER OF SILICA DEPOSITED ON ITS SURFACE [BADANIE ODPORNOSCI HYDROLITYCZNEJ SZKLA PLASKIEGO SODOWO-WAPNIOWEGO Z WARSTWA KRZEMIONKOWA NANIESIONA NA JEGO POWIERZCHNIE]

Malgorzata Wolna, Joanna Szwedowska-Kotlinska, and Waclaw Tuszynski 1991 22 p In POLISH

(IFTR-34/1991) Avail: CASI HC A03/MF A01

A discussion of the possibility for enhancing the resistance of a hydrolytic surface with a deposited silicon layer is discussed. The silicon layer was deposited on plane surfaces of soda glass by submersion in diluted soda-silicon aqueous solutions. The hydrolytic resistance was analyzed in accordance with the Standard DIN 52 296 (Hydrolytic resistance of the surface of glass and glass ceramic plates at 98 C. Method of test and classification for the hydrolytic resistance of the surface of glass and soda glass plates.) Since the quantity of recovered N22O from the surface of the soda-glass reaches 120 micrometers - 2. Immediately following additional treatment of the glass surface in boiling water, this quantity dropped to 30 micrograms/dm2. The silicon layer established on the surface of the plane soda glass increases the hydrolytic resistance of the glass and also induces a hydrolytic phase change from hp3 to hp2. Transl. by FLS

APPLICATION OF HARD COATINGS TO SUBSTRATES AT LOW TEMPERATURES Final Report

William D. Sproul 15 Jun. 1993 57 p

(Contract NAS8-37686)

(NASA-CR-193867; NAS 1.26:193867) Avail: CASI HC A04/MF A01

BIRL, the industrial research laboratory of Northwestern University, has conducted unique and innovative research, under sponsorship from the NASA Marshall Space Flight Center (MSFC), in the application of hard, wear resistant coatings to bearing steels using the high-rate reactive sputtering (HRRS) process that was pioneered by Dr. William Sproul, the principal investigator on this program. Prior to this program, Dr. Sproul had demonstrated that it is possible to apply hard coatings such as titanium nitride (TiN) to alloy steels at low temperatures via the HRRS process without changing the metallurgical properties of the steel. The NASA MSFC program at BIRL had the specific objectives to: apply TiN to 440C stainless steel without changing the metallurgical properties of the steel; prepare rolling contact fatigue (RCF) test samples coated with binary hard coatings of TiN, zirconium nitride (ZrN), hafnium nitride (HfN), chromium nitride (CrN), and molybdenum nitride (MoN), and metal coatings of copper (Cu) and gold (Au); and develop new alloyed hard coatings of titanium aluminum nitride (Ti(0.5)Al(0.5)N), titanium zirconium nitride (Ti(0.5)Zr(0.5)N), and titanium aluminum vanadium nitride. APPLICATION OF THERMAL SPRAY AND CERAMIC COATINGS AND REINFORCED EPOXY FOR CAVITATION DAMAGE REPAIR OF HYDROELECTRIC TURBINES AND PUMPS Final Report

Richard Ruzga, Paul Willis, and Ashok Kumar Mar. 1993 52 p

(AD-A267624; CERL-TR-FM-93/01) Avail: CASI HC A04/MF A01

The U.S. Army Corps of Engineers is one of the largest single producers of hydroelectric power in the United States. The Corps' ability to generate power can be reduced by cavitation in hydroelectric turbines. Cavitation is the damage that results from high velocity liquid flow and pressure changes. Cavitation can be repaired by traditional methods, such as welding or application of epoxy, or by the newer non-fusion methods, such as thermal spray and the use of reinforced epoxies. This research shows that the performance of reinforced epoxies is sensitive to surface preparation and method of application. Repair by these compounds lasts from 6 months to 1 year, but the downtime for repair is very short. New thermal-sprayed metallized coating systems have been tested in the laboratory and show potential for application in cavitation repair. New ceramic coatings have improved cavitation resistance, but their application is limited by current thermal spray technology, which is improving. DTIC

INVESTIGATION OF THE OPTICAL, ELECTRONIC, AND STRUCTURAL PROPERTIES OF FIBER OPTIC GLASSES Final Report, 19 Dec. 1989 - 28 Feb. 1993

J. A. Frietas, Jr. Jun. 1993 175 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-90-C-2020)

(AD-A267645; SFA-93/002) Avail: CASI HC A08

Under contract N00014-90-C-2020, SFA provided research support to the Naval Research Laboratory Electronic Materials Branch by conducting investigations on novel materials. These investigations ranged from using various techniques to characterize the optical, electronic, and structural properties of this semiconductor films to setting up a micro-Raman and microphotoluminescence laboratory to study microcrystalline films. The materials studied include heavy metal fluoride glasses, chalcogenide glasses, silicon carbide, diamond (chemical vapor deposition films, high-pressure, high-temperature synthetic and natural), and aluminum nitrides. These materials were investigated by such optical techniques as Raman scattering (RS), photoluminescence (PL), photoluminescence excitation, absorption, reflectivity, electron spin resonance (ESR), photo-induced ESR, optically detected magnetic response (ODMR), and Hall measurement. FABRICATION OF PIEZOELECTRIC CERAMIC/POLYMER COMPOSITES BY INJECTION MOLDING Final Report
15 Apr. 1993 47 p
(Contract N00014-92-C-0010)
(AD-A267302) Avail: CASI HC A03/MF A01

Piezoelectric ceramic/polymer composites have many applications in advanced Navy transducers and commercial ultrasonic imaging. Unfortunately, their application has been limited by the lack of a manufacturing-viable technology capable of meeting both the low cost and high volume production requirements. The principal manufacturing difficulty lies in the handling of millions of fine PZT fibers during their assembly into a typical composite transducer installation. In this program, Materials Systems Inc. (MSI) has demonstrated that ceramic injection molding is capable of meeting the stringent transducer cost and assembly needs of piezoelectric ceramic/polymer composites for Navy applications. The injection molding approach overcomes the difficulty of assembling oriented ceramic fibers into composite transducers by net-shape performing ceramic fiber arrays. Aside from this advantage, the process makes feasible the construction of composite transducers having more complex ceramic element geometries than those previously envisioned, leading to greater design flexibility for improved acoustic impedance matching, lateral mode cancellation and superior actuator performance. DYNAMIC TESTING AND CHARACTERIZATION OF PRE-FRACTURED CERAMIC
A. K. Zurek and D. A. Hunter 1993 5 p Presented at the 14th International Conference on High Pressure Science and Technology and 1993 Technical Meeting of the Topical Group on Shock Compression of Condensed Matter, Colorado Spring, CO, 28 Jun. - 3 Jul. 1993
(Contract W-7405-eng-48)
(DE93-016457; LA-UR-93-2334; CONF-9306167-6) Avail: CASI HC A01/MF A01

Nearly all of the mechanical behavior studies of armor ceramics, to date, have involved the characterization and testing of pristine ceramic material. However, ballistic impact causes a strong shock front to propagate rapidly through the ceramic before much penetration can occur. A strong shock wave can result in localized compressive failure and fragmentation of the ceramic before its amplitude is annuated below the compressive strength of the ceramic. Goals of this effort were to create shock-fractured ceramic using test assemblies which maintain the intergranular coupling and high density of the ceramic, characterize the extent and homogeneity of the fragmentation and dilatation of the ceramic, and test the compressive dynamic behavior of the shock-fractured ceramic under conditions of confining pressure. This effort will provide data to support models of the penetration resistance of fractured ceramics including degraded moduli, failure strength-strain, and post-failure characterization of the erosive properties of comminuted ceramic and penetrator materials. CERAMIC FIBER COATINGS DEVELOPMENT AND DEMONSTRATION Final Technical Report, 1 Jul. 1989 - 31 May 1993
H. Streckert, D. Hazlebeck, F. Montgomery, K. Norton, and I. Schneir 28 May 1993 206 p
(Contract F49620-89-C-0078)
(AD-A267286; GA-C21284; AFOSR-93-0499TR) Avail: CASI HC A10/MF A03

The objective of this program was to develop fiber coating techniques by gas phase and liquid phase processes for interface control in ceramic matrix and metal matrix composites. Thermochemical evaluations of fiber/coating/matrix systems were performed theoretically and experimentally. Liquid phase processes were developed mainly for oxide coatings. Gas phase processes were developed for carbide, nitride, and boride coatings. Coatings were produced on continuous fiber tows and woven fabric. A small scale continuous fabric coater was designed and constructed. Coated fiber tows were infiltrated with silicon nitride matrix by chemical vapor deposition in order to study fiber matrix interactions. Composite coupons were made from Nicalon cloth and infiltrated with silicon nitride. Samples coated with high temperature BN showed flexural strengths up to 350 MPa. DTIC

EVALUATION OF INTERFACIAL PROPERTIES OF FIBER-REINFORCED CERAMIC COMPOSITES USING FIBER PUSH-IN TESTS
C. H. Hsueh 1993 12 p Presented at the 95th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 18-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015427; CONF-930438-25) Avail: CASI HC A03/MF A01

Evaluation of the interfacial properties of fiber-reinforced ceramic composites using fiber push-in tests is addressed. The stress-displacement relation of the embedded fiber subjected to an axial loading-unloading cycle is analyzed. The interfacial bonding, Coulomb friction at the debonded interface, Poisson's effect on the loaded fiber, and residual stresses are included in the analysis, and closed-form analytical solutions are obtained. Based on the analytical solutions, a methodology is established to extract the interfacial properties from the experimental stress-displacement curves. Roles of interfacial bonding, Poisson's effect, and residual axial stresses on residual fiber displacement after complete unloading are also addressed in the present study. DOE

SYNTHESIS, CHARACTERIZATION, AND POLYMERIZATION OF NEW FERROCENE-FLUORENE COMPLEXES. A NOVEL HIGH-MOLECULAR WEIGHT CONJUGATED POLYMER WITH PENDANT FERROCENE GROUPS
Michael E. Wright and Brooks B. Cochran 1992 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267717) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Ferrocenecarboxaldehyde was successfully condensed with fluorene derivatives to afford a series of new complexes, (eta5-C5H5) Fe(eta5-C5H4CH = (9-fluorenyl)) where fluorenyl = 1A, 2-bromo: 2a, 2,7-dibromo; 3, 2-nitro. The ferrocene-fluorenyl derivatives Ia and 2a were converted to the monocarboxaldehyde, tributylstannyl, bis(carboxaldehyde), and bis(tributylstannyl) complexes (Ib, Ic, 2b, and 2c, respectively). Complexes Ib and 2b were characterized by single-crystal x-ray molecular structures. The fluorenyl ring systems were tilted out of the eta5-C5H4 plane by 39 deg. Treatment of Ic and 2c with I2 afforded the mono- and bis(iodo)fluorenyl complexes Id and 2d, respectively. The reactivity of complexes 2a-d was explored. The alkynylation (alkyne, L2PdCl2, CuI, PPh3) of 2a was an extremely poor reaction giving little or no cross-coupling. Complex 2b did not undergo the Knoevenagel polycondensation with bis(cyanoacetate) comonomers. Treatment of 2c with acid chlorides under Stille cross-coupling conditions afforded ketone product and iodobenzene showed no cross-coupling. Complex 2d did copolymerize very cleanly with 2,5(diethynyl)-1,4-(decoxy)benzene using palladium catalysis to afford a soluble, high-molecular weight conjugated polymer, 4. A model compound, 5, was prepared from cross-coupling Id with 2, 5-(diethynyl)-1, 4-(decoxy)benzene. DTIC

SYNTHESIS OF NOVEL ELECTRICALLY CONDUCTING POLYMERS: POTENTIAL CONDUCTING LANGMUIR-BLODGETT FILMS AND CONDUCTING POLYMERS ON DEFINED SURFACES Final Report
Hans Zimmer 17 Nov. 1993 51 p
(Grant NAG3-995)
(NASA-CR-194651; NAS 1.26:194651) Avail: CASI HC A04/MF A01

Based on previous results involving thiophene derived electrically conducting polymers in which it was shown that thiophene, 3-substituted thiophenes, furans, and certain oligomers of these compounds showed electrical conductivity after polymerization. The conductivity was in the order of up to 500 S/cm. In addition, these polymers showed conductivity without being doped and most of all they were practically inert toward ambient conditions. They even could be used in aqueous media. With these findings as a guide, a number of 3-long-chain-substituted thiophenes and 1-substituted-3-long-chain substituted pyrrols were synthesized as monomers for potential polymeric electrically conducting Langmuir-Blodgett films.

DIAMOND GROWTH ON CARBIDE SURFACES USING A SELECTIVE ETCHING TECHNIQUE
K. J. Grannen and R. P. Chang Jul. 1993 30 p
(Contract N00014-89-J-1848)
(AD-A267989; TR-14) Avail: CASI HC A03/MF A01

Microwave plasma-enhanced chemical vapor deposition of diamond films on silicon carbide and tungsten carbide (with 6% cobalt) surfaces using fluorocarbon gases has been demonstrated. No diamond powder pre-treatment is necessary to grow these films with a (100) texture. The diamond films are characterized by scanning electron microscopy and Raman spectroscopy. The proposed nucleation and growth mechanism involves concurrent etching of the non-carbon component by atomic fluorine and deposition of diamond. Hydrogen is necessary in the growth process to limit the rapid etching of the substrate by fluorine atoms. DTIC

HIGH TEMPERATURE DEFORMATION BEHAVIOR OF YBa2Cu3O(6+x) SUPERCONDUCTING CERAMIC MATERIALS
A. S. Rao, L. F. Aprigliano, and O. P. Arora 15 May 1993 38 p
(AD-A268164; CDNSWC/SSM-61-93/18) Avail: CASI HC A03/MF A01

Superplastic deformation is being explored as a means to turn the new ceramic superconducting YBa2Cu3O(6+x) into useful Naval hardware. The deformation experiments that were conducted on fine YBa2Cu3O(6+x) powders suggest that the maximum deformation that can be achieved without the degradation of superconductivity is about 62% at 850 C. The addition of silver improves the maximum deformation, and the addition of alumina has a devastating effect on the deformation mode. DTIC

(AD-A268401; WL-TR-93-2068) Avail: CASI HC A03

Polymers having transport almost exclusively of the ionic type, often named polymer electrolytes or, in a broader way, polymer ionics, have attracted large scientific and technological interest. Research on this new class of electroactive polymers has been very active and substantial progress has been achieved in recent years. Of particular interest are the new generation polymer electrolytes formed by the immobilization into a polymer matrix of common solutions of lithium salts in liquid, organic solvents. This new class of gel electrolytes offers very high ambient and subambient conductivities. In this project, we have carried out a preliminary investigation of the electrochemical properties of a typical example, namely of the membrane electrolyte obtained by gelification into a polyacrylonitrile (PAN) matrix of solutions of lithium salts (e.g., LiCl04) in aprotic solvents (e.g., an ethylene carbonate-propylene carbonate mixture). The choice was motivated by the fact that membranes of this type appear to be closest to reach a practical exploitation. DTIC

There are many possible effects of interface reactions in fiber or whisker reinforced glass or glass ceramic matrix composites. In most cases, interface reactions must be minimized because they can lead to degradation of fiber or whisker strength, destruction of interphase coatings, and modification of the interface adhesion. Nevertheless, there are systems where interface reactions are beneficial. The best example of this is in the NiCALON reinforced glass-ceramic composites where carbon interphases are generated during processing; this carbon interphase facilitates fiber pullout and thereby, is responsible for the outstanding room-temperature toughness of these materials. There have also been suggestions, although less well documented, that interface reactions can create carbide, nitride and mullite interphases that passivate the interface to subsequent oxidation. (AD-A267966) Avail: CASI HC A03/MF A01

Monocrystalline films of SiC were grown on alpha (6H)-SiC(0001) wafers using disilane (Si2H6) and ethylene (C2H4) by gas-source MBE at 1050 deg C. The nucleation and growth of cubic beta-SiC(111) on the surface terraces of the hexagonal 6H-SiC rather than on the step surfaces and the resultant formation of double positioning boundaries is discussed. The reconfiguration of the growth system leading to enhanced control over polytype deposition is also described. Thin film contacts of Ti, Pt, Hf, and Co were deposited in UHV onto unheated, n-type vicinal alpha(6H)-SiC(0001) films by electron beam evaporation. All as-deposited contacts were rectifying with low ideality factors (n less than 1.1), low leakage currents and Schottky barrier heights between 0.85 eV and 1.15 eV. The lowest leakage currents were less than 5x10(exp -8) A/CM2 at -10V. Titanium and Pt remained relatively stable after annealing at 700-750 deg C; whereas, Co became ohmic after annealing for two minutes at 1000 deg C. UV photoemission studies on both SiC/metal interfaces and the surface of AlN(0001) deposited on SiC have been initiated. A major emphasis is on surface cleanliness prior to metal deposition. A spectral feature observed in the AlN is attributed to the initial indication of negative electron affinity in this material. Chemical interdiffusion between alpha (6H)-SiC wafers and epitaxially deposited 2H-AlN films are under investigation within the temperature range of 1500 deg C to 1700 deg C. DTIC

SOLUBLE PRECURSOR ROUTE TO POLYANILINES Final Report, 1 Sep. 1991 - 29 Feb. 1992
Floyd L. Klavetter Jan. 1993 9 p
(Contract F49620-91-C-0092)
(AD-A268015; AFOSR-93-0572TR) Avail: CASI HC A02/MF A01

To achieve the fundamental goal of producing a processible form of the conducting polymer polyaniline (PANI), the phase 1 program concentrated on development of the synthesis of a precursor polymer via the solution co-polymerization of bis(annellated) benzoquinone with p-phenylenediamine. The resulting polymer, expected to be soluble in common organic solvents, would be converted to PANI by thermal elimination of the pendant

cyclopentadiene groups following processing. Attempts to carry out the proposed polymerization reaction using conventional methods for ketone-amine condensation were not successful, and resulted in the conclusion that bis(annellated) benzoquinone is too 'crowded' a ketone for the polycondensation chemistry. HEATING OF LUBRICANT WITH AN ELECTRIC RESISTANCE HEATER [VOITELUOELJYN LAEMMITTAEMINEN SAEHKOEVASTUKSELLA]

Matti Kytoe Apr. 1992 34 p In FINNISH Sponsored by Technology Development Center, Finland, and Finnish Industry Original contains color illustrations

(VTT-TIED-1359; ISBN-9-51-384172-3; ETN-93-94477) Copyright Avail: CASI HC A03/MF A01

Heating of lubricant with electric resistance can result in oil cracking, and consequently, in changes in lubricant properties and in lubricant fouling. In the worst case an explosible gas mixture is formed from the cracking products in the lubricant tank or in the object of lubrication. In the experiment, three transmission oils with high pressure additives and one circulation lubricant were heated with an electric resistance heater. The aim was to determine the limits of problem free heating and to study changes in the lubricant during cracking. The lubricant is cracked and the heated coked in continuous heating of dozens of hours duration as soon as the temperature rises to 70 to 100 C. Circulation lubricant stands long term heating at a surface effect of less than 2 W/sq cm when the temperature of the lubricant is lower than 85 C. The corresponding temperature limit for the gear oil is about 60 C. The difference is due to additives; a significant part of the foul on the surface of the resistance is due to lubricant additives. The experiment indicated that short term heating does not result in oxidation of the lubricant or in the fouling of the heating resistance. In two hour tests the maximum temperature of the lubricant was 80 C and the maximum hydrocarbon content of tank air 200 ppm. In long term tests no coking appeared with less than 300 ppm hydrocarbon contents. Heating of lubricant even at temperatures below the pour point does not cause problems. The temperature peaks at the start of heating are short term, and no heater coking or lubricant cracking appears. Formation of an explosive mixture from the cracking products is possible only if the heater is coked very strongly, when the surface temperature under the foul rises even as high as to 300 C. Strong coking can be observed only as an increase in the hydrocarbon content of the tank air or as a rise in the surface temperature of the resistance heater, while the temperature of the lubricant remains stable. Spectroscopic evidence is presented that shows that boron nitride and aluminum oxide can be synthesized by exposing a condensed layer of molecular precursors to synchrotron radiation. In the Al2O3 circumstance a condensed layer of trimethylaluminum (TMA) and water at 78 K on a silver substrate produces pure layers of aluminum oxide. Using the same condensed layer technique, boron nitride is produced by exposing a solid matrix of diborane and ammonia to synchrotron radiation. Near edge x-ray absorption fine structure and core level photoelectron spectroscopies are used to characterize the Al2O3 and BN layers, which were typically 30 A thick. During the formation of aluminum oxide, the carbon component in the alkylaluminum precursor is completely removed during irradiation as a volatile methane product which was detected by mass spectrometry. In the absence of synchrotron radiation, the molecular precursors in both the aluminum oxide and boron nitride systems show evidence of some interactions within the solid, but upon warming to near room temperature (260 K) the layers desorb from the substrate. HIGH OCTANE ETHERS FROM SYNTHESIS GAS-DERIVED ALCOHOLS
K. Klier, R. G. Herman, M. A. Johansson, and O. C. Feeley Apr. 1993 26 p
(Contract DE-AC22-90PC-90044)
(DE93-016861; DOE/PC-90044/9-Rev-1) Avail: CASI HC A03/MF A01

The objective of the proposed research is to synthesize high octane ethers, primarily methyl isobutyl ether (MIBE) and methyl tertiary butyl ether (MTBE), directly from H2/CO/CO2 coal-derived synthesis gas via alcohol mixtures that are rich in methanol and 2-methyl l-propanol (isobutanol). The overall scheme involves gasification of coal, purification and shifting of the synthesis gas, higher alcohol synthesis, and direct synthesis of ethers. The testing of strongly acidic catalysts for the conversion of a mixture of methanol and isobutanol to ethers and hydrocarbons was continued. Under standardized test conditions the catalysts tested this quarter were: phosphotungstic acid supported on zirconia (PW12/ZrO2), 'niobic acid' (Nb2O5 (center dot)xH2O), and an iron and manganese doped sulfate modified zirconia (Fe/Mn/ ZrO2/ SO4(sup 2-)). The overall activity of these catalysts followed the order of Fe/Mn/ ZrO2/ SO4(sup 2-) greater than PW12/ZrO2 greater than Nb2O5 (center dot)xH2O with the Fe/Mn/ ZrO2/ SO4(sup 2-) catalyst approaching ZrO2/SO4(sup 2-) in both activity and selectivity for isobutene production. The effect of the presence of water on the reaction of methanol and isobutanol over ZrO2/ SO4(sup 2-) was determined to be insignificant under the reaction conditions investigated. DOE

DENSIFYING AND STABILIZING INGREDIENT Patent
Craig E. Johnson, inventor (to Navy) and Paul F. Dendor, inventor (to Navy) 9 Mar. 1993 4 p Filed 6 Nov. 74
(AD-D015751; US-Patent-5,192,379; US-Patent-Appl-SN-521977) Avail: US Patent and Trademark Office

This invention relates to explosives and more particularly to that branch of explosives known as propellants, wherein the propellants are those stabilized and densified with at least one lead fluoride. In the explosive field there are four general subdivisions - (1) primary explosives, (2) secondary explosives, (3) pyrotechnics, and (4) propellants. The primary explosives are generally very sensitive and serve to initiate other less sensitive explosives. A secondary explosive has high brisance and shattering power but little propelling power. Most secondary explosives are usually less sensitive than primary explosives and require a primary explosives to initiate them. DTIC

ADVANCED THERMALLY STABLE JET FUELS
H. H. Schobert, S. Eser, C. Song, P. G. Hatcher, P. M. Walsh, M. M. Coleman, J. Bortiatynski, C. Burgess, R. Dutta, and K. Gergova et al Feb. 1993 131 p
(Contract DE-FG22-92PC-92104)
(DE93-017711; DOE/PC-92104/T1) Avail: CASI HC A07/MF A02

The Penn State program in advanced thermally stable coal-based jet fuels has five borad objectives: (1) development of mechanisms of degradation and solids formation; (2) quantitative measurement of growth of sub-micrometer and miocrometer-sized particles suspended in fuels during thermal stressing; (3) characterization of carbonaceous deposits by various instrumental and microscopic methods; (4) elucidation of the role of additives in retarding the formation of carbonaceous solids; and (5) assessment of the potential of production of high yields of cycloalkanes by direct liquefaction of coal. Pyrolysis of four isomers of butylbenzene was investigated in static microautoclave reactors at 450 C under 0.69 MPa of UHP N2. The rates of disappearance of substrates were found to depend upon the bonding energy of C(alpha)-C(beta) bond in the side chain in the initial period of pyrolysis reactions. Possible catalytic effects of metal surfaces on thermal degradation and deposit formation at temperatures greater than 400 C have been studied. Carbon deposition depends on the composition of the metal surfaces, and also depends on the chemical compositions of the reactants. Thermal stressing of JP-8 was conducted in the presence of alumina, carbonaceous deposits recovered from earlier stressing experiments, activated carbon, carbon black, and graphite. The addition of different solid carbons during thermal stressing leads to different reaction mechanisms. C-13 NMR spectroscopy, along with C-13-labeling techniques, have been used to examine the thermal stability of a jet fuel sample mixed with 5% benzyl alcohol. Several heterometallic complexes consisting of two transition metals and sulfur in a single molecule were synthesized and tested as precursors of bimetallic dispersed catalysts for liquefaction of a Montana subbituminous and Pittsburgh No. 8 bituminous coals. The synthesis of multigram quantities of 1,3,3- trimethyl cyclopropene was accomplished using a modified literature procedure. The stability of this material towards different conditions was studied. Oxygen reacts with the neat material to quickly form a thick polymeric gum which eventually solidifies to a white solid. In the presence of Lewis acids such as untreated glass or metals such as stainless steel or copper, neat cyclopropene will form a 2+2 dimeric product in high yield. Hydrocarbon solutions (e.g. RP-1) of the cyclopropene are much more stable to these mild Lewis acid conditions but will also produce the dimeric product. A multigram sample of the cyclopropene was sent for testing in the microthruster at Phillips Laboratory. A convenient large scale synthesis of 3-chloro- 2-chloro methyl propene was developed starting with pentaerythritol. This compound serves as the starting material for a two step synthesis of 1.1.1 propellane. DTIC

The detection of voids in SRM propellant is critical to the safety of Launch Vehicles. Currently this is done with the use of x-rays as an NDE technique. It is hoped to supplant this technique with the use of ultrasonic NDE methods for reasons of reduced cost, increased mobility of the NDE set-up, automated accept/reject criteria, to name a few. To be feasible the ultrasonic NDE methods must be to differentiate between a through-transmission signal from an SRM propellant segment with a void, and a signal from a segment without a void. The ability of ultrasonic NDE to penetrate one meter of propellant has already been demonstrated with sufficient signal-to-noise ratio. The crux of the ultrasonic NDE method will be in using the information present in the received signal to detect, locate, and size voids. DTIC

Ignition experiments on nitrate-ester and nitramine propellants have been conducted in a closed bomb. The ignition source was a variable cw C02 laser. Ambient conditions were room temperature and atmospheric pressure. Air, argon, and nitrogen gases were used. Times to detect and changes in emission rate which are attributed to onset of flamespreading have been compared with ignition delay calculations using a condensed phase radiant ignition model. Reasonable values for thermochemical properties and experimental determined values for chemical kinetic parameters and optical properties were used for the calculations. The flux dependence of the initial emission delays were in reasonable agreement with model predictions for nitrate-esters but not for nitramines. Gas phase (composition) effects on initial emission were observed with XM39, an RDX nitramine, but not with nitramines. Flamespreading delays showed gas composition effects with all propellants. These results suggest that (for all propellants) the effects of gas phase reactions on flamespreading and (for nitramines) on initiation need to be included (explicitly) in radiant ignition models for predicting pressurization in gun chambers. Directional solidification experiments have been utilized throughout the Materials Processing in Space Program to provide an experimental platform which minimizes variables in solidification experiments. Because of the wide-spread use of this experimental technique in space-based research, it has become apparent that a better understanding of all the phenomena occurring during solidification can be better understood if direct visualization of the solidification interface were possible. The following represents a summary of progress made on the project 'Evaporation from a Capillary Meniscus in Microgravity' being conducted at the University of Dayton during the period 1 Dec. 1992 to 30 Nov. 1993. The efforts during this first year of the grant focused upon the following specific tasks: (1) application of a 3-D scattering particle image velocimetry technique to thin film velocity field measurement; (2) modeling the thermo-fluid behavior of the evaporating meniscus in 0-g within large diameter capillaries; (3) conceptualization of the space flight test cell (loop) configuration; (4) construction of prototypes of the test loop configuration; (5) conduct of experiments in 0-g in the 2.2 second drop tower at NASA-LeRC to study evaporation from a capillary meniscus within a square cuvette; and (6) investigation of the effect of vibrations on the stability of the meniscus. An overview of the work completed within these six task areas is presented. Author (revised)

PRIORITIZATION METHODOLOGY FOR CHEMICAL REPLACEMENT
W. Cruit, S. Schutzenhofer, B. Goldberg, and K. Everhart Oct. 1993 66 p Sponsored by NASA, Washington
(NASA-TP-3421; M-732; NAS 1.60:3421) Avail: CASI HC A04/MF A01

This project serves to define an appropriate methodology for effective prioritization of efforts required to develop replacement technologies mandated by imposed and forecast legislation. The methodology used is a semiquantitative approach derived from quality function deployment techniques (QFD Matrix). This methodology aims to weigh the full environmental, cost, safety, reliability, and programmatic implications of replacement technology development to allow appropriate identification of viable candidates and programmatic alternatives. The results are being implemented as a guideline for consideration for current NASA propulsion systems. Author

The NASA Office of Space Science and Applications (OSSA) has developed a strategic plan providing for an integrated program that includes extending OSSA's research infrastructure beyond existing ground-based, suborbital, Shuttle, and Spacelab facilities. OSSA intends to move to develop facilities that will take advantage of the unique resources to be provided by Space Station Freedom. The Station will provide the opportunity for in-depth space research in a microgravity environment. The pressurized volume of the Station will house microgravity science and applications (MSA) and life science experiments, conducted almost entirely within experiment racks that line the pressurized modules. MSA and life sciences facilities and research goals within the space station program are outlined. Other divisions of NASA will utilize the Station's attached payload capability to carry out research in the fields of astrophysics, earth science, solar and planetary physics, space plasma physics, and communications and information systems. Future evolution of Station research facilities and utilization concerns are discussed. Author (CISTI)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

In the Columbus space station Attached Laboratory, there will be 40 experiment racks but less than two crew members available to tend them, meaning that experiment operations cannot be permanently performed by the crew. The Columbus Free Flyer will be a completely automated laboratory, serviced periodically by astronauts. To facilitate the running of experiments in the Columbus facilities, the telescience concept will be used extensively. Telescience provides ground-based users with interactive and transparent access to their on-orbit experiments. Data such as telemetry and video are received by the user, who then can react by sending telecommands to activate mechanisms or robotic systems to operate the experiment. To validate the telescience concept, to promote it, and to train telescience users, a testbed has been developed and installed. The testbed has integrated five pilot experiments operated through a user workstation. The testbed has also been used in an operational simulation of long-duration space missions. A flight test of a telescience experiment investigating Marangoni convection was performed in Nov. 1989 onboard a sounding rocket with complete success. Author (CISTI)

Japan will participate in space station research by means of the Japanese Experiment Module (JEM). Utilization conditions for JEM are being investigated through preliminary surveys and a number of initiatives have been undertaken to prepare for JEM utilization. A design reference mission has been studied which includes those themes expected to receive favorable effects from a microgravity environment. Some key experimental technologies common to various research themes are being developed using reduced gravity experiments in the MU-300 jet aircraft and in a sounding rocket program. Some Japanese programs using Spacelab are also under development. Systematic research themes selected as candidate groups from a design reference mission include production of semiconductors and high purity materials, studying of natural convection and crystal growth, and measuring diffusion coefficients in a liquid phase. CANADIAN MICROGRAVITY EXPERIMENTS FLOWN IN 1989-1990
Ron Wilkinson and Glen S. Campbell *In its* Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Canadian microgravity experiments flown from Apr. 1989 to Mar. 1990 included one on the Biocosmos satellite, launched for 14 days in Sep. 1989. This experiment studied the development of osteoblast progenitor cells obtained from rats flown in space. The majority of microgravity work was done on two sets of flights using NASA's KC-135 reduced gravity aircraft. Canadian experiments on the KC-135 are reviewed in the areas of data acquisition, life science, materials science, biotechnology, dynamics, and education. Topics of specific experiments included the following: eye movements, blood volume distribution, arm movements, grain refining in alloys, liquid/liquid phase separation, production of microspheres and metal foams, laser drilling and welding, bubble coalescence, protein crystallization, gyroscope drift, and production of educational video modules.

The study of fundamental combustion and fluid physics phenomena in microgravity enables a new range of experiments to be performed since buoyancy-type flows are nearly eliminated, normally obscured forces and flows may be isolated, gravitational settling or sedimentation is nearly eliminated, and larger time or length scales in experiments become permissible. Some new phenomena found through ground-based microgravity research at NASA facilities is reviewed along with the instrumentation and drop tower facilities used in the research. Experiments are described in the areas of premixed gas combustion, droplet combustion, particle cloud combustion, liquid reorientation, and two-phase flow patterns. Future plans for instrumentation development are also outlined. Author (CISTI)

LASER-LIQUID INTERACTIONS UNDER REDUCED GRAVITY CONDITIONS
R. E. Mueller and W. W. Duley *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 5 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

An experiment was performed under microgravity conditions in a KC-135 flight to study the heat transfer and resultant mass flows in a two-phase system subjected to laser radiation. A special cell was constructed to hold liquid water and to keep the water surface at the focus of the laser beam,

an aluminum insert was used. A hole in the insert was large enough to provide a free water surface but small enough so that the surface tension would restrain the water against small upward accelerations. The results show the differences in behavior of bubbles generated by the laser beam under the reduced gravity and high gravity conditions encountered during the flight. Under normal gravity, a trapped bubble may form below the conically shaped hole formed by the laser beam in the water. Under high gravity, the bubble appears smaller and sits deeper in the cell and has a much shorter lifetime. Under reduced gravity, the bubble is unconstrained by pressure and buoyant forces and was observed to grow to 2.5 times the diameter of a bubble in normal gravity. The penetration depth of the laser drill cone does not appear to be greatly affected by the presence or absence of gravity. Author (CISTI)

THE VIBRO-ACOUSTIC MAPPING OF LOW GRAVITY TRAJECTORIES ON A LEARJET AIRCRAFT

C. M. Grodsinsky and T. J. Sutliff *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 8 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The NASA LeRC Learjet aircraft is used to fly parabolic trajectories for carrying out in-flight microgravity experiments. To derive full benefit from data obtained in such experiments, it is not only required to understand the low- to moderate-frequency accelerations present but also necessary to characterize the broadband aircraft vibro-acoustic environment. A vibro-acoustic measurement program was conducted during a series of low-gravity trajectories flown on the Learjet. The fuselage and an experiment rack were instrumented with 13 channels of accelerometers and three channels of pressure transducers. The locations of these sensors were determined in order to build a time history of the dynamics involved in the flight of such a parabolic trajectory and thus determine the typical rigid-body and vibro-acoustic loading a payload would experience. The instrumentation, data acquisition sequence, and experimental results showing residual accelerations and high-frequency dynamics are presented. As suspected, the measurements revealed that the aircraft environment cannot simply be described in terms of the static level low-gravity g-vector obtained, but that it also must account for both rigid-body and high-frequency vibro-acoustic dynamics. MAXUS: THE NEW SOUNDING ROCKET PROGRAM FOR LONG DURATION MICROGRAVITY FLIGHT

Lennart Bjorn *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 6 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

MAXUS provides easily accessible, cost-effective suborbital microgravity flight opportunities of longer duration than the seven minutes typical of existing sounding rockets. The program is jointly conducted by the Swedish and German space organizations and uses a newly developed guided sounding rocket to launch microgravity payloads of 680 kg to an altitude of 875 km, giving 14.5 minutes of exoatmospheric microgravity conditions. The payload accommodates some 420 kg of scientific experiments and is based on a modular design that allows flexibility in the configuration of each individual payload and makes testing easy and reliable. The first MAXUS launch is scheduled for the spring of 1991 and will be followed by at least one launch per year from the ESRANGE launch site in northern Sweden. A well-proven land recovery system provides rapid and reliable retrieval of samples. The telemetry and telecommand system of MAXUS provides for extensive use of telescience, enabling experimenters to have hands-on control and observation of microgravity experiments.

DEVELOPMENT OF THE LASER-BASED R/D TEST-BED SYSTEM (LTS)

M. Olivier, S. Simard, L. Audet, A. Laferriere, and W. Jamroz *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 6 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The laser-based research and development testbed system (LTS), supported by Canadian Space Agency programs, is a modular multi-user research system based on commercially available components for use on the variable gravity environment provided by the NASA KC-135 aircraft. The LTS consists of seven basic units: the supporting structure, the integrated laser unit, the beam delivery unit, power supply, control and data acquisition unit, material processing unit, and the optical diagnostic unit. The units are described along with some planned experiments that will make use of LTS capabilities. The LTS is designed so that several types of laser systems can be used: CO2, He-Ne, argon, and excimer lasers.Some of the subjects to be studied using the LTS include the following: laser melting or quenching of metals and welding of thin metal sheets in near-zero gravity; laser interactions with water; laser welding of plastics and glasses; vacuum materials processing; laser chemical vapor processing; and mass spectroscopy analysis. OPTICAL SYSTEMS FOR THE VISUALIZATION OF FLUID AND SOLID TRANSPARENT MEDIA UNDER MICROGRAVITY CONDITIONS c35

E. Harvey and P. Langlois *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 8 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Canada's National Optics Institute carried out, on behalf of the Canadian Space Agency, a study on the diagnosis of fluids under reduced gravity using new optical technologies. The Institute is conducting research on the adaptation of optical fluid diagnostic techniques to the visualization of laser processing of plastic in microgravity. Continuation of this project should lead to a KC-135 flight involving the optical diagnostic system. A short overview is presented of the optical techniques for fluid analysis including new techniques introduced within the last decade. Arguments are stated which lead to the choice of real-time holographic interferometry and Moire deflectometry as the most suitable techniques with respect to microgravity experiment requirements. Preliminary results are also presented from ground experiments with gas, liquid, and acrylic media. The results indicate that the two selected techniques allow visualization of temperature fields, hot spots, and convection currents with a very high sensitivity. A better understanding of the underlying phenomena can thus be acquired.

QUESTS: A MICROGRAVITY RESEARCH FACILITY FOR MATERIALS SCIENCE EXPERIMENTS

G. Tyc, D. Gates, R. W. Smith (Queens Univ., Kingston, Ontario.), S. Goodman (Queens Univ., Kingston, Ontario.), and K. N. Tandon (Manitoba Univ., Winnipeg.) *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 8 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The QUESTS (Queen's University Experiment on the Space Transportation System) payload has a modular design to increase payload application flexibility and its controller software is also flexible in order to accommodate a large variety of materials science experiments. The QUESTS payload has evolved through several phases of study to the current configuration, which consists of three gradient-freeze furnaces conducting unidirectional freezing experiments and twelve isothermal furnaces conducting liquid diffusion experiments. The payload consists of the following major subsystems: experiment hardware, payload control and data acquisition electronics, power supply, and ground support equipment. The payload is 9.5 m in diameter, 0.68 m high, and has a mass of 90 kg. QUESTS is designed for use on space shuttle flights, but could also be used on KC-135 aircraft flights and, with minor modifications, on a sounding rocket.

PAYLOADS FOR THE PROCESSING OF HIGH TEMPERATURE MATERIALS
S. E. Prasad, M. Verghese, A. Roorda, K. Slaughter, I. Murley, P. Stern, and P. Lave *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Payloads designed for microgravity processing of high temperature materials are described. The payload for use in the KC-135 aircraft includes a power supply, electronic controller, kiln, sample storage magazine, and cooling unit. The magazine can store up to eight samples and is operated by simple push-pull levers. The payload was designed to fulfill criteria including operator and aircraft safety, ease of operation, and reliability. The payload for use in the T-33F aircraft is designed to be fully automatic and can be preprogrammed to suit a broad range of experimental processes. Extremely rapid temperature cycling is possible and a closed-loop system ensures that the specimens are contained at all times, reducing the fire hazard. The payload apparatus consists of a furnace system, power supply and relay switches, and programmable logic control system. The payload for use on the Black Brant sounding rocket consists of a furnace, battery box, and card cage holding the control circuitry. The apparatus was designed to process glasses but could be modified to accommodate other materials. For ground experiments, an aerodynamic levitation unit has been developed which permits containerless processing of samples up to 6 mm in diameter. During experiments, a solid sphere sample is levitated and melted using a high intensity lamp and parabolic mirrors. Author (CISTI)

THE CANADIAN SPACE STATION USER DEVELOPMENT PROGRAM. WHERE DO WE GO FROM HERE? **c18**
Parvez Kumar *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 3 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The Canadian Space Station User Development Program (UDP), formally approved in March 1986, is gradually approaching maturity. As a result of limited funding, it is also approaching saturation. The remaining UDP budget is $60 million and there are no funds to build space-qualified hardware. Successful microgravity experiments in aircraft have shown that 20 seconds of microgravity are adequate for doing useful science in most cases. Spinoffs have already occurred through applications of patents for processes discovered during microgravity related work. A number of unsuccessful attempts have been made to establish drop-tube test facilities in Canada, and efforts are being made within UDP to acquire first-hand knowledge of such facilities through cooperative programs with other countries. A microgravity rocket was scheduled for a fall 1991 launch but enough experiments may not be found. The CANEX 2 flight on the space shuttle is already fully subscribed, and Canadian scientists are slowly beginning to get aboard the shuttle as co-investigators. It has been decided to book one locker on the October 1993 SPACEHAB flight. Over the long term, the high costs of participating in the space station are of concern. It is recommended that the UDP continue with its microgravity work but only use the space station on an as-required basis. Author (CISTI)

CONTAINED LIQUIDS IN MICROGRAVITY, PART 2
In National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

An experiment was designed to study the effects of microgravity on the behavior of contained liquids varying in viscosity, surface tension, miscibility, molecular size and shape, intermolecular forces, and molecular mass. The experimental apparatus consisted of cylindrical cavities of varying diameter cut into plexiglass, enclosed with glass plates. Additional variations included triangular and square shapes, and different cell linings. The behavior of the liquids was recorded by video camera. The liquids chosen included lubricating oils, methyl alcohol, glycerol, ethylene glycol, saline and sucrose solutions, sodium oleate, mineral oil/water, ethyl alcohol, water, and oleic acid. Experiments were conducted during microgravity flights of the KC-135 aircraft, and results of experiments using ethylene glycol and methyl alcohol mixtures with air are reported. It is suggested that observed encapsulation of air in ethylene glycol was artificially induced by the flight conditions and that true encapsulation resulting from capillary action under microgravity was only exhibited by methyl alcohol. STUDY OF FRACTAL AGGREGATES [ETUDE DES AGREGATS FRACTALS]
C. Rioux, L. Potvin, and R. J. Slobodrian *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 4 p In FRENCH (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The properties of fractals are defined and the method of calculating fractal dimension is introduced, along with illustrative examples. Applications of knowledge about fractals are discussed and results of experiments in forming fractals are presented. Such applications include the description of particle behavior in air, the compression of information for satellite transmission, and the formation of crystals under gravitational forces. In the experiments, fractal structures were formed by depositing a fine powder suspension in water and by a chemical reaction between silver nitrate and copper. For producing fractal structures in microgravity, a literature review reveals one method which is readily applicable to use in space. The method consists of heating a filament previously coated with metal and evaporating this metal in the form of droplets, which then aggregate in the presence of a helium cooling gas. INVESTIGATION OF TWO-PHASE FLOW AND BOILING HEAT TRANSFER DURING QUENCHING OF A TUBE UNDER MICROGRAVITY
M. Kawaji, C. J. Westbye, and B. N. Antar (Tennessee Univ. Space Inst., Tullahoma.) *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 4 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

There are many important processes that occur under microgravity which would involve gas-liquid two-phase flow and boiling condensation heat transfer phenomena. For example, in refilling of space vehicles with liquid hydrogen or oxygen under microgravity, a transient quenching process is expected involving two-phase flow and convective boiling heat transfer due to the low boiling points of the fluids and high initial wall temperatures of the refuelling lines and receiving tanks. To elucidate the behavior of two-phase flow patterns under quenching conditions, a series of quenching experiments will be performed during microgravity flights of the KC-135. The experimental apparatus consists of a compact test loop incorporating a quartz tube test section which is heated externally. The tube contains a low boiling point refrigerant at near atmospheric pressure. When microgravity conditions are reached, a pump will inject the liquid into the tube, and the flow and heat transfer phenomena will be recorded. Results are presented from pre-flight tests conducted to obtain reference data at 1 gravity.

USE OF MICROGRAVITY IN THE SYNTHESIS OF CERAMICS USING SOL GEL TECHNIQUES
L. M. Luckevich, V. R. Trimble, and B. G. Sellars *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 6 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Using sol-gel processing techniques, it is possible to prepare sub-micron ceramic oxide powders with a narrow particle size distribution. This permits sintering to high density at lower temperatures, and allows fabrication of ceramic bodies with improved microstructures and distributions of phases. The use of microgravity to produce uniform ceramic spheres of greater

than 1 mm diameter was investigated in order to understand the kinetics of formation for terrestrial process applications and to assess application of the technology to space processing of ceramic powders and products. The sol-gel method used in the investigation was the polymerized alkoxide process, in which metal alkoxides are partially hydrolyzed or decomposed, then recombined by polymerization to form a metal-oxygen bond. Using this process in microgravity, spherical droplets are formed and there is no gravity-induced movement of the polymerizing particle. If the period of microgravity is long enough, complete reaction to the center of the particle is possible. In microgravity experiments aboard the KC-135 aircraft, several techniques for sphere production were developed, including a sphere growth and pulse-off method, a jet formation method, and an oscillating jet method. GAS BUBBLE GENERATION AND TRANSPORT IN MICROGRAVITY

Z. Abdullah and M. Salcudean *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

An investigation is being conducted to develop a technique to inject and transport gas bubbles in liquid metals and then to quench the metal to form a porous solid. The objective is to vary the porosity as a function of the spatial location in a predictable and controllable manner, such that the more highly stressed parts of the solidified product would have a low void fraction and lower stressed regions would have a higher void fraction. Such a technique would only be feasible in microgravity, and in order to determine the influence of the various parameters involved in such a process, the generation and transport of gas bubbles in microgravity was studied aboard flights of the KC-135 and T-33 aircraft. The test cell consisted of an 8-cm square plexiglass enclosure containing a water-glycerine electrolyte. A well controlled flow field was established in the electrolyte using a magnetohydrodynamic pump. Gas bubbles were injected into the electrolyte using a vibrating gas injector. The gas bubble formation and movement was recorded on video. Several distinct trends were observed and simple models are presented to explain the trends. The models explain bubble detachment, breakup, and spacing. Model predictions are strongly supported by experimental observations. Author (CISTI)

KC-135 ACCELERATION MONITORING AND DATA ACQUISITION SYSTEM **c05**

Bjarni V. Tryggvason and Patrick J. Sullivan *In its* Proceedings of the Second Workshop on Microgravity Experimentation 1990 3 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The KC-135 data acquisition system is a comprehensive data collection system designed and built for the purpose of microgravity research aboard the NASA KC-135 aircraft. The system consists of the necessary hardware for basic signal processing and an interactive software package which provides for custom specification of data collection requirements. The primary use of this system will be to monitor, record, and provide signals to other researchers of aircraft accelerations along three axes, and interior pressure, temperature, and humidity. Several data channels will also be available to record data from experiments aboard the aircraft. The components of this system are described, including the power supply, computer system, signal conditioning unit, software, and accelerometers. The system has been successfully flight-tested. INFRA LINK: A DATA TRANSMISSION SYSTEM FOR MICROGRAVITY RESEARCH **c32**

Bill Stewart, Mike Hollingshead, Jennifer Stinn, Dennis Michaelson, and Bjarni Tryggvason *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 5 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

In microgravity experiments conducted during parabolic flight in aircraft, the experimental equipment may be freely floated in the aircraft cabin in order to improve the g-levels for the experiment. If it is necessary to transmit and/or receive data from the apparatus, a data link which does not defeat the free floating nature of the experiment is needed. In addition, in experiments where physiological data are collected from human subjects in near-weightless conditions, it is convenient to have a data link that does not require a complex and awkward umbilical cord connecting the subject to the data recording system. To this end, a data transmission system has been developed which uses infrared light as the data transmission medium. The system, called InfraLink, was designed to be able to operate and store data for at least two hours, to be compact, to be a standalone system not requiring any operator intervention during the flight, and to have a multichannel capability. The system was tested on the ground and during KC-135 flights to evaluate the range and quality of the infrared link. Results are presented showing data dropout and error rates. The results demonstrate the feasibility of the InfraLink as a data collection system for KC-135 flight experiments. Author (CISTI)

REAL TIME RADIATION MEASUREMENTS IN SPACE **c93**

I. Thomson and G. Mackay *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 3 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Radiation composed of energetic electrons, protons, photons, and galactic cosmic rays will be experienced by all space missions and may have effects on radiation sensitive electronic components and biological specimens. Radiation issues of interest to microgravity and biological experiments are discussed and the design of a new direct reading electronic radiation monitoring system is described. The proposed system consists of a radiation sensitive metal oxide semiconductor field effect transistor (MOSFET) specially designed to respond to ionizing radiation. On exposure to radiation, a permanent charge is stored in the MOSFET's insulating oxide, altering the device's electrical characteristics in a manner directly proportional to the dose exposed. A simple circuit reads the MOSFET's cumulative dose, making it possible to obtain real-time measurements and store the data or transfer the data to an earth station. Tests have shown that the MOSFET dosimeter shows a linear response up to at least 30,000 centiGray at a resolution of 0.1 centiGray. The MOSFET dosimetry system will be installed on the European Space Agency's ARTEP satellite scheduled for launch in November 1991. Author (CISTI)

CHARACTERISTICS OF AIMED ARM MOVEMENTS IN HUMANS UNDER LOW GRAVITY **c54**

O. Bock, K. Arnold, I. Howard, and K. Money *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 3 p (For primary document see N94-16071 03-29)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

A study was conducted to investigate the accuracy of arm pointing movements in human subjects without visual feedback on the pointing arm during low-gravity episodes of KC-135 flights, in order to gather new information on errors of visual localization and of movement execution in space. The experimental setup involved pointing at the face of a digitizing pad mounted on the back of a computer screen that provided the pointing target and faced the human subject. The time between target appearance and movement onset (reaction time), movement duration, movement velocity, and absolute pointing errors were recorded. A clear tendency was found to point too high or low in the first movement of each low-gravity episode, and to reduce these pointing errors during subsequent movements. No changes in movement kinematics between low-gravity and normal gravity were observed. Author (CISTI)

Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Small N techniques are known by such names as single system, interrupted time series, intrasubjects replication designs, single subject, or idiographic research. These techniques are ideal for application to the microgravity life sciences field, where large N studies are not feasible because they would be extremely costly and take years to conduct. Small N study techniques are the only viable method for obtaining the optimum scientific value from studies performed on the limited number of subjects in the limited time available in microgravity. The small N techniques are dependent on establishing a basic level of the dependent variable for each subject, then introducing the independent variable to determine whether there is a change in the dependent variable. Steps to be used in performing small N studies in practice are outlined. Author (CISTI)

Transcranial doppler ultrasound (TCD) was used to measure blood flow velocities in the middle cerebral artery of volunteers subjected to 15-20 seconds of acute microgravity in the NASA KC-135 aircraft. In addition, simultaneous recordings of acceleration in the z direction and of other systemic vascular parameters were obtained. In-flight experimental procedures and the development of a system for recording and processing a large volume of data are described. Problems in performing the experiments and in analyzing the data are noted. Results of processing seven subjects indicate a change in the quantitative indices during the flight. Of particular interest are the changes in received power of the Doppler signal and the mean flow velocity waveforms in the microgravity regions. Indices related to the mean flow of the artery appear to exhibit changes in each phase of the flight parabola that are consistent from subject to subject.

Ocular counterrolling is a reflex rotation of the eyes about the visual axis opposite to the lateral inclination of the head. Attempts were made to measure the static and dynamic components of ocular counterrolling during the hypogravity and hypergravity phases of parabolic flight, using the electromagnetic scleral search-coil technique. The results provide evidence that torsional eye displacements occurred in response to the imposition of altered gravitoinertial forces. The torsional position of the eyes is not constant, when the subject's head position, both during upright or tilt, is maintained. In some subjects, the torsional displacement in microgravity is accompanied by a fine torsional nystagmus. Also, the direction and magnitude of the torsion differ substantially from one individual to another. There was a significant difference in torsional magnitude between the microgravity and hypergravity period in all head positions. Under 1-g condition, static counterroll compensated for about 16% of head roll while the dynamic counterpart was much larger, up to 36%. The gain of dynamic counterroll was also higher during the hypergravity phases than the microgravity phases. Author (CISTI)

The Bubble Detector Spectrometer (BDS) was developed primarily for the measurement of degraded fission neutrons. The Canadian Space Agency obtained a modified BDS to be used for measurement of the neutron spectrum in space. The energy responses of the five types of space BDS were measured using monoenergetic neutrons, and the measured response functions are presented. Two sets of BDS detectors were delivered, along with six pairs of bubble detectors, for placement in the Biocosmos-2044 satellite. After return of the satellite, the bubble detectors were retrieved and sent for data retrieval and processing. Spectral data from the Biocosmos bubble detectors are presented and discussed. Preliminary results show a large number of neutrons above 10 MeV, and another component spanning 0.1 to 10 MeV which bears some resemblance to an evaporation spectrum. The neutron spectrum was similar at the three locations in the satellite where the bubble detectors were located. At the location close to the small hatch, the neutron dose was comparable to that at the location of the BDS, or 82 millirems. At the other location of the dosimeter package, the dose was only 37 millirems. Author (CISTI)

HEART RATE RESPONSE TO PARABOLIC FLIGHT MANOEUVRES **c52**
Daryl Leiski, Igor Makjavic, and B. V. Tryggvason *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 9 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Some of the physiological data on heart rate response to parabolic flight maneuvers are analyzed. Data were gathered from two subjects on flights of the KC-135 aircraft over a two year period. The electrocardiogram data retrieval system and statistical analysis methods used are described. Results are presented and discussed for heart rate versus time and versus acceleration. Heart rate versus time showed no conclusive trends. The heart rate versus acceleration levels illustrated the results that were expected based on previous studies using tilt tables to alter the hydrostatic column. The heart rate changes are directly linked to the changing hydrostatic column and the resulting fluid shifts. Coupled with this bioreceptor response is the exercise reflex, a response to the static muscular contraction of the abdominal and leg muscles maintaining body posture through the high-g portions of the parabolas. Comparison of responses between the two subjects provides insight into interindividual differences in responses to the stress of parabolic flight. Author (CISTI)

FINITE ELEMENT ANALYTICAL TECHNIQUES FOR CERAMIC PRODUCTION IN MICROGRAVITY: A HYPOELASTIC MODEL
F. Taheri and J. G. Murphy *In its* Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

Slipcasting is useful for fabricating complex structural shapes from materials such as aluminum oxide. There are many mechanisms that can generate shrinkage cracks in slipcast ceramic components, including the

residual stresses caused during the drying and firing stages of fabrication. The ceramic firing cycles necessary for sintering often produce high thermal gradients and can cause differential densification rates, resulting in formation of residual stress patterns. The methodology used in evaluating the effects of microgravity on slipcast ceramics are discussed, with the aim of increasing understanding of microstructural effects in microgravity. The analysis used the finite element method in conjunction with a hypoelastic material constitutive model. The qualitative results obtained from a preliminary run of the finite element model using the ABAQUS software package illustrate that this numerical methodology can be used to emulate the sintering mechanism and estimate the residual stresses caused by the firing process. PRECISE MEASUREMENT AND UTILIZATION OF ACCELERATION DATA **c19**
L. Potvin, C. Rioux, and R. J. Slobodrian *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 5 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

The causes of the main perturbations of the reduced gravity environment in a spacecraft in low earth orbit are examined. These include the variations in the earth's gravitational field, imbalances between gravitational and inertial forces, effects of the residual atmosphere, effects of solar radiation and micrometeorites, and man-made effects such as use of thrusters and movements of spacecraft personnel. To understand results of experiments carried out in this microgravity environment, an accurate record of these perturbations is needed. Specifications for a sensor of microgravity perturbations are outlined and the design of some existing accelerometers is assessed for their possible application in such a sensor. A new concept for a compact, high sensitivity accelerometer is proposed in which a small iron rod in equilibrium inside a solenoid is used. Suggestions are made for the organization and presentation of acceleration data from the proposed accelerometer system. Author (CISTI)

THE DESIGN AND ANALYSIS OF A MODULAR MICROGRAVITY TEST PLATFORM FOR USE ABOARD THE NASA KC-135 AIRCRAFT **c18**
Alain Durand, Roger Hertz, Darren Mitchell, and Kamiel S. Rezkallah *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 7 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

A microgravity platform to be used for housing experiments aboard the NASA KC-135 aircraft was designed using a modular construction approach. Two identical modules were designed to be used in three basic configurations: side by side, vertically stacked, or separately mounted. The levels within each module were adjustable and removable, providing yet another means by which the platform could be altered to suit the experiment being conducted. The frame was designed according to the strict strength and safety specifications set out by NASA. Additional design objectives stipulated that the frame be versatile, light weight, and accessible to the experiment operator. The ANSYS finite element stress analysis package was used to simulate the frame structure and its various components. Internal moments and forces were obtained from the finite element model and were later compared to the results from material performance tests. The results indicated that the platform could withstand the gravity levels experienced on the aircraft, including crash loads, with sufficient factors of safety. Author (CISTI)

SOLUTION BEHAVIOUR IN MICROGRAVITY: CONSIDERATIONS FOR PROTEIN CRYSTAL GROWTH
Christin T. Choma *In* National Research Council Canada, Proceedings of the Second Workshop on Microgravity Experimentation 1990 5 p (For primary document see N94-16071 03-29)
Avail: Issuing Activity (National Research Council, Publication Sales and Distribution, Montreal Road, Ottawa, Ontario, K1A OR6 Canada)

X ray crystallography can provide high resolution atomic structures of biological macromolecules such as proteins, but the technique requires uniform, large crystals of the biochemical. There is evidence that microgravity is more conducive than 1-g to the growth of protein crystals suitable for x ray analysis. Injector materials were identified which are suitable for producing the large, stable protein drops required for crystal growth. Experiments were conducted on flights of both T-33 and KC-135 aircraft involving injectors in various configurations. Protein and precipitant solutions were brought to mix together in three ways and the results were recorded on video. The results indicate that protein and precipitant solutions must be actively mixed prior to being extruded into a pendant crystallization droplet in microgravity. In the absence of density driven convection, diffusion alone is insufficient to bring about mixing. Author (CISTI)

This guide provides the technical information required to implement the application of hot-mix recycling of asphalt concrete pavements. Included are details on application, benefits/advantages, limitations/disadvantages, and costs associated with this technology. Information is provided on three demonstration sites at Fort Gillem, Georgia; Fort Leavenworth, Kansas; and Fort Benjamin Harrison, Indiana. Also provided is information concerning funding, procurement, maintenance, and performance monitoring. A fact sheet on recycling, contract specification example, and references are provided in the appendices. DTIC

MATHEMATICAL MODEL OF FROST HEAVE AND THAW SETTLEMENT IN PAVEMENTS
Gary L. Guymon, Richard L. Berg, and Theodore V. Hromadka Apr. 1993 135 p
(AD-A267037; CREEL-93-2) Avail: CASI HC A07/MF A02

Since 1975 the U.S. Army Corps of Engineers, the Federal Highway Administration and the Federal Aviation Administration have been working cooperatively to develop a mathematical model to estimate frost heave and thaw weakening under various environmental conditions and for various pavement designs. A model has been developed. It is a one-dimensional representation of vertical heat and moisture flux. It is based on a numerical solution technique termed the nodal domain integration method, and it estimates frost heave and frost penetration reasonably well for a variety of situations. The model is now ready for additional field evaluation and implementation in appropriate cases. The main objectives of this report are: (1) to describe the model, FROST, including modeling uncertainties and errors; (2) to summarize recent comparisons between measured and computed values for frost heave and frost penetration; and (3) to describe parameters necessary for input into the model. A process for slip casting ceramic articles that does not employ parting agents and affords the casting of complete, detailed, precision articles that do not possess parting lines is presented. This process is especially useful for high temperature superconductors and water-sensitive ceramics. A wax pattern for a shell mold is provided, and an aqueous mixture of a calcium sulfate-bonded investment material is applied as a coating to the wax pattern. The coated wax pattern is then dried, followed

by curing to vaporize the wax pattern and leave a shell mold of the calcium sulfate-bonded investment material. The shell mold is cooled to room temperature, and a ceramic slip, created by dispersing a ceramic powder in an organic liquid, is poured therein. After a ceramic shell of desired thickness or a solid article has set up in the shell mold, excess ceramic slip is poured out. The shell mold is misted with water and peeled away from the ceramic article, after which the ceramic is fired to provide a complete, detailed, precision, high temperature superconductive ceramic article without parting lines. The casting technique may take place in the presence of a magnetic field to orient the ceramic powders during the casting process. NASA

The focal activities of the research establishment and its alignment in the innovation strategy of the Krupp Group are described. Research and development plays a key role in the constant process of product and production renewal. Technological and market influences must interact in the innovation process in such a way that market needs, with ever shorter product life cycles, can be met. Factors leading to innovative success are discussed. These include: a comprehensive organizational concept to ensure smooth translation of Research and Development (R and D) work into products and processes; the continual reassessment of technical and economic risks; and the interplay of strategic planning control, marketing and technology. The organization of the centralized R and D, as undertaken at Krupp, which represents a powerful strategic element in the development and exploitation of technological synergies is discussed. The specialist capability at Krupp is said to embrace the following key technology categories: information technology and automation; mechanical engineering and process technology; and materials and components. The use of Vacuum Plasma Spraying (VPS) as a method of coating materials to protect them against wear is discussed. Vacuum plasma spraying offers a range of interesting applications which have yet to be fully exploited. Apart from conventional applications, such as wear and corrosion protection in the form of high density coatings with good bonding properties, vacuum plasma spraying can also be used to manufacture complex components with graded structures. The plasma jet can also be used for materal synthesis, for example, for producing pure diamond coatings from gaseous carbon carriers. ESA

INTEGRATION TOOLKIT AND METHODS (ITKM) MANUFACTURING METHODS AND PROTOTYPE TOOLKIT. A COMBINED MODELING METHOD USING IDEFO, IDEF1x AND XSpec Final Report, Jun. 1991 - Jun. 1992
Jul. 1992 52 p
(Contract F33615-91-C-5725)
(AD-A266176; ITI-CR-92-57A; WL-TR-93-8019) Avail: CASI HC A04/MF A01

This report develops the major theoretical concepts for the integration of three diverse engineering modeling languages: IDEFO, IDEFIx, and XSpec. IDEFO is a high level modeling tool based on functional decompositions, IDEFIx is a detailed data modeling tool, and XSpec is a simulation tool based on object-oriented decompositions. The approach used to integrate the tools is to develop a meta-model of the three modeling languages. These meta-models are examined, and a single combined meta-model is developed. All three systems use the same combined meta-model. This ensures that any changes to the system made in one language is reflected in the other languages automatically. A short description of each of the languages is given. These are not intended to be exhaustive, they are provided so that the reader is familiar with the terminology used in each of the methods and to get a feel of the types of models each language produces. The meta-models of IDEFO and XSpec are given. The approach

used to develop the combined meta-model is given. Finally, a complete description of the meta-model is presented. DTIC

A MEASUREMENT STATION FOR STUDY OF EARTH MOVING TOOLS AND GROUND CUTTING PROCESSES [STANOWISKO POMIAROWE BADANIA NARZEDZI DO ROBOT ZIEMNYCH I PROCESOW SKRAWANIA GRUNTU]

Wieslw Trampczynski, Leszek Pionecki, Julian Cendrowicz, and Dionizy Szyba 1991 65 p In POLISH

(IFTR-10/1991) Avail: CASI HC A04/MF A01

The construction and operation of a measurement station to study processes of cutting soils is discussed. It is comprised of three independent sections: simulation studies mainly of motion kinetics environment during the cutting process; studies on a semitechnical scale of both the forces acting on the tools and the kinematics of the process; and studies of the kinematics and dynamics of fittings of a hydraulic excavator with particular attention to tool/environment interaction. In the last two sections, a hydraulic drive was used with complete computer control in a closed system. The computer system also permitted collecting and processing experimental data. Transl. by FLS

DRY STRIPPING AS A SURFACE TREATMENT METHOD [MUOVIRAEPUHALLUS PINNANKAESITTELYMENETELMAENAE]

Ilkka Nieminen Mar. 1992 72 p In FINNISH Sponsored by Finnish Industry, and Technical Research Centre of Finland, Espoo

(VTT-TIED-1348; ISBN-9-51-384161-8; ETN-94474) Copyright Avail: CASI HC A04/MF A01

High environmental and safety standards as well as use of new paint and substrate materials have created the need for developing stripping methods to substitute chemical and mechanical methods and on the other hand for expanding the applicability of blasting as a surface treatment. Plastic Media Blasting (PMB) (alternatively Dry Stripping System (DSS)) is an emerging technology first used in aircraft maintenance for paint stripping. Traditionally this task is performed by brushing and grinding or by using chemical solvents. With plastic media it is possible to remove thick paints with high adhesion without damaging the substrate and even layer by layer. If suitable type of plastic media, blasting pressure low enough, media concentration high enough and on the other right blasting time, blasting distance and blasting angle are chosen, the effectiveness of PMB can be varied to a large extent. In regard to the hardness of media plastic particles are situated between some organic materials and shots used in sand blasting. Therefore composite materials can be treated without damaging the substrate or thin metal plates without causing any deformations. The principle of plastic media blasting equipment is similar to traditional blasting

equipment. Nevertheless the properties of plastic media are different to harder particles used in shot peening resulting in higher demands for filtration, ventilation and recycling systems. In addition the facilities have to contain proper recovery equipment, because plastic media can be reused, even 20 times. In recycling systems plastic media is cleaned, too large and too small particles are removed, hard and magnetic particles are removed from reusable media and dust is separated from media. In addition to paint stripping PMB can successfully be used for cleaning of surfaces from contamination and to some extent for polishing, grinding and roughening. Paint stripping has been the main application so far, but there may be many other possibilities to apply the method in the future. However the PMB is not the only new technology for stripping problems. Some interesting investigations were performed for using frozen carbon dioxide, soda or high pressure water jet for paint stripping. ESA

A NOVEL SOLID-STATE OPTICAL TEMPORAL ANALYZER WITH PICOSECOND RESOLUTION AND PICOWATT SENSITIVITY Final Report, 1 Jul. 1992 - 1 Apr. 1993
Steven Williamson 30 Apr. 1993 29 p
(Contract DAAL03-92-C-0035)
(AD-A266804; ARO-30499.1-EL-SBI) Avail: CASI HC A03/MF A01

The goal of this Phase I SBIR program was to demonstrate the feasibility and characterize a novel picosecond optical temporal analyzer based on a new 1-ps resolution photodetector. The detector/analyzer system integrates the photodetector on the same chip with a similar laser activated sampling gate. The sensor is called a Sampling Optical Temporal Analyzer, or SOTA. We have fabricated and tested this device to determine its ultimate speed, sensitivity, and dynamic range. The SOTA's system response was found to be 1.4 ps with a sensitivity of 100 pW. This is the world's fastest, most compact, ultrasensitive, picosecond optical waveform analyzer. It is completely solid-state and has a measured dynamic range of 80 dB. The potential of this technology for dual-use applications is extensive, reaching into the medical, scientific, optical communications, and automotive industries. The speed, sensitivity, and dynamic range of the SOTA, coupled with its ability to be mass produced using conventional microfabrication, offers us a unique opportunity to develop a new and greatly advanced high speed optoelectronic sensor technology. ANTENNA GAIN LOSS AND PATTERN DEGRADATION DUE TO TRANSMISSION THROUGH DIELECTRIC RADOMES M.S. Thesis
Karl A. Klopp Mar. 1993 122 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267242) Avail: CASI HC A06

A computer model for axially symmetric dielectric radomes in the near field of a circular aperture has been developed. This model, based on a method of moments solution for bodies of revolution, is used to determine the electric field pattern of a linearly polarized circular aperture radiation through a dielectric radome. The program is written in FORTRAN and can accommodate rotationally symmetric radome shapes. Arbitrary illumination distributions for the aperture can be specified, and phased scanning of the aperture in both azimuth and elevation is allowed. Computational run time has been reduced by taking advantage of mode symmetry, A separate program has been developed to compute gain, and together these programs are used to determine the pattern degradation and gain loss due to the presence of a radome in the near field. AN OPTICALLY MODULATED SCATTERER FOR MICROWAVE ANTENNA METROLOGY
Graham Hygate May 1993 135 p
(NPL-DES-126; ETN-93-94553) Copyright Avail: Issuing Activity
(National Physical Lab., Teddington, Middlesex TW11 OLW, England)

An optically modulated dipole scatterer was developed to be used monostatically to measure microwave frequency electric field distributions. The same probe may be used over an entire waveguide band (for example, 8.5 to 12.0 GHz) and a single detection apparatus was constructed to cover the frequency range 2 to 18 GHz. The technique is particularly well suited to measuring the electric field close to conductors, where conventional techniques fail. Near field antenna measurements require exactly this capability, and the technique was used successfully to obtain the far field radiation patterns of a horn antenna by near field measurement and transformation. The chief advantages of the optically modulated scatterer over conventional methods of near field scanning are minimal perturbation of the field by the probe and the lack of any systematic phase error due to flexing of cables during the near field scan. WINDSHEAR RADAR CALIBRATION, 1992 FLIGHTS: TRANSMITTER POWER AND RECEIVER GAIN STABILITY
Anne I. Mackenzie Aug. 1993 10 p
(RTOP 505-64-12-02)
(NASA-TM-108997; NAS 1.15:108997) Avail: CASI HC A02/MF A01

During the 1992 NASA airborne Doppler windshear radar flights, radar calibrations were performed prior to each flight in order to determine transmitter power, receiver gain, and receiver noise power. The calibration results show that the average transmitter power in radar mode 6 was 186 watts, with a standard deviation of 7 watts. The average high power amplifier gain was 9.62 dB. At the wide IF bandwidth setting, the receiver gain was 123.1 dB, while at the narrow IF bandwidth setting, the gain was 121.8 dB. The receiver system noise as seen at the receiver input was -107.0 dBmw using the wide IF bandwidth and -107.9 dBmw using the narrow IF bandwidth. In radar mode 7, the receiver gain was the same as in mode 6. However, the receiver noise in mode 7 was about 2.5 dB less using the wide IF bandwidth and 2.0 dB less using the narrow IF bandwidth. The R/T unit flown in 1992 had also been flown the previous year when it produced comparable results. This technical memorandum was written as a follow-up to NASA TM-107589 (June 1992), which describes similar radar calibrations performed during the 1991 windshear radar flight experiments. Author

Multipath propagation of an airport secondary radar is analyzed by means of a theoretical model for reflection and diffraction. A lossy dielectric rectangular plate placed perpendicular to the flat ground was chosen for modeling a reflecting building facade. Diffraction diagram was calculated with the Fresnel-Kirchhoff approximation. The geometry factor of the reflection plane was calculated with a second order Taylor development around the virtual mirror reflection point, so that two Fresnel integrals with simple coefficients were obtained. The following possible ground reflections were discussed: reflection of the electromagnetic wave on the ground only, single reflection at the building face, and double reflection at ground and building facade. Interference of direct and ground reflected fields, reflection and diffraction from an isolated rectangular plate (azimuth and elevation diagrams) and influence of reflections from a flat surrounding ground were calculated. THE NEXT GENERATION WEATHER RADAR (NEXRAD)/AIR ROUTE SURVEILLANCE RADAR (ARSR) OPERATIONAL COMPARISON Final Report
Brian Dunbar and Jeff Mittelman Jul. 1993 99 p Original contains color illustrations
(Contract DTFA01-93-C-00001)
(Rept-93W0000145; DOT/FAA/SE-93/4) Avail: CASI HC A05/MF A02

The National Weather Service (NWS), Federal Aviation Administration (FAA), and Department of Defense are in the process of fielding the Next Generation Weather Radars (NEXRAD). These doppler weather radars, also known as Weather Surveillance Radar (WSR)-88D, will be replacing the WSR-57 and WSR-74 weather radars in use today. The NEXRAD data will be used by the FAA's Advanced Automation System (AAS) in place of the Air Route Surveillance Radar (ARSR) weather data currently being used by air traffic controllers. Because the NEXRAD's scanning strategy is more time consuming than the ARSR's, there have been some concerns expressed within the FAA about using 'untimely' NEXRAD data in an Air Traffic Control (ATC) environment. In response to these concerns, the FAA's Center for Advanced Aviation System Development (CAASD) at MITRE conducted a study, under the sponsorship of the FAA's National Airspace System (NAS) System Engineering Service (ASE), to assess the relative ability of NEXRAD's and ARSR's to detect and present significant weather in order to determine the operational impact of using NEXRAD data in lieu of ARSR data. The NEXRAD/ARSR operational comparison study is documented. Author (revised)

JOHNSON-GIERHART PROGRAM PREDICTIONS OF EXCESS PROPAGATION LOSS FOR SUPER-HIGH FREQUENCY AIR-TO-GROUND PATHS. VOLUME 2: APPENDICES Final Report
Melvin M. Weiner and John C. Herther Jun. 1993 223 p
(Contract F19628-89-C-0001)
(AD-A267021; MTR-92B0000027V2; ESC-TR-93-161-Vol-2) Avail: CASI HC A10/MF A03

The Johnson-Gierhart tropospheric propagation program of the Institute for Telecommunications Sciences is used to obtain predictions of excess propagation loss over that of free space for super-high frequency (SHF) air-to-ground paths within or on the radio horizon. The principal loss (gain) mechanisms considered are atmospheric absorption and refraction, surface multipath interference, smooth spherical Earth diffraction, and single knife-edge diffraction caused by terrain roughness and/or a site-specified obstacle. The program uses a semi-empirical database to statistically weigh the losses from these mechanisms. The excess propagation loss increases with increasing range and can exceed 3 decibels at distances as close as halfway to the radio horizon. DTIC

COMPARISON OF RADARC HIGH-FREQUENCY RADAR PERFORMANCE PREDICTION MODEL AND ROTHR AMCHITKA DATA
Benjamin T. Root and James M. Headrick 16 Jul. 1993 62 p
(AD-A267077; NRL/MR/5320-93-7181) Avail: CASI HC A04/MF A01

Data collected with AN/TPS-71 radar has been used to validate the RADARC model. For the first ten days of Jan., Apr., and Jul., noon and midnight, the vertical ionograms, oblique backscatter soundings, radar ground backscatter amplitudes, and noise levels have been compared with Model predictions. The differences between the Model and median ionospheric soundings are small enough to have negligible effect on predictions. The coverage predicted for oblique backscatter soundings agrees well with observed median data except for sporadic E effects which were under-estimated. Medians of observed ground backscatter agree fairly well with predictions. The actual noise that controlled radar performance was the most significant deviation from the model. All nighttime and January day noise was higher than that predicted; and this was due to 'multiplicative' noise. DTIC

ADAPTIVE BEAMFORMING WITH IMPERFECT ARRAYS: PATTERN EFFECTS AND THEIR PARTIAL CORRECTION Report, Sep. 1991 - May 1992
Lars E. Pettersson Dec. 1992 106 p
(AD-A267079; RL-TR-92-341) Avail: CASI HC A06/MF A02

The effects of various types of imperfections on the radiation pattern of adaptive antenna arrays, using the Applebaum and Frost algorithms, are investigated. The imperfections considered are nonuniform noise figures in the channels, gain and phase shift error, IQ imbalance, DC offset, finite number of samples when forming the covariance matrix, quantization of the signals, and the weights and saturation of the signals. In particular the effects on the resulting sidelobe level, null depth, and gain are studied, and simulated results and analytical expressions for the expected pattern parameters are given. The effects of some methods to partly correct for the imperfections are also investigated. A method to obtain low sidelobe pattern when using the Frost algorithm is also discussed. DTIC

BROADBAND CONVENTIONAL BEAMFORMING INCORPORATING ADAPTIVE EQUALIZATION Final Report, Jan. - Sep. 1992
Richard C. North Sep. 1992 45 p
(AD-A267090; NRAD-TR-1575) Avail: CASI HC A03/MF A01

This report discusses methods which attempt to coherently recombine the spatially and temporally different multipaths with the direct path to enhance array gain. These methods are based on utilizing a broadband conventional beamformer incorporating adaptive equalization to recombine multipath information. Preliminary results are compared with two well-known narrow-band, purely spatial processing techniques: the Bartlett beamformer; and the minimum variance distortionless response beamformer. While preliminary results are promising, several important research issues are outlined which remain to be addressed. DTIC

Experience gained with the European Communications System (ECS) satellites during the ninth year of service in orbit from the beginning of Jul. 1991 to the end of Jun. 1992 is summarized. Appraisals are made of how various individual satellite systems have performed taking into account: thermal control; telemetry, tracking and command; attitude and orbit control and reaction control; and power. Significant events during the reporting period are identified. The accumulated total of channel years of the ECS system at the end of Jun. 1992 was close to 215, considerably in excess of the original Eutelsat requirement upon ESA to provide a minimum of 180 channel years. In the reporting period, the ECS system accumulated a total of 256,447 channel hours, or 29 channel years. Only seven of the total of 22 Spurious Switch Offs (SSO's) interrupted traffic. The total outage time due the SSO's was 29.1 channel minutes. ESA

DETERMINATION OF THE ELECTROMAGNETIC FIELDS RADIATED FROM THE ARES EMP SIMULATOR Technical Report, 1 Sep. 1991 - 31 Dec. 1992
Fred M. Tesche and Charles T. Mo 1 Jul. 1993 67 p
(Contract DNA001-88-C-0046)
(AD-A267069; RDA-TR-2-2240-1704-0001; DNA-TR-92-153) Avail: CASI HC A04/MF A01

This report describes a calculational model for evaluating the electromagnetic (EM) fields produced by the ARES simulator outside its normal working volume. The model employs transmission line theory to determine the simulator current distribution. Once this is determined, the radiated fields are computed approximately using the Norton surface-wave formalism. The transient electric and magnetic fields on the ground are calculated using a fast Fourier transform (FFI) and are compared with experimental magnetic field data. Accuracies on the order of 30% in the peak fields are noted in much of the data. The fields in the air above the earth also have been calculated, and the relative importance of the Norton surface wave in the overall solution has been clarified. This model and its resulting PC code provide a useful tool for further studies of the impact of radiated EM fields on distant electrical systems. The results presented here are directly applicable in defining and evaluating the EM environments produced by ARES, or by similar bounded wave simulators, and in assessing and limiting the possible biological effects of pulsed radiation. EXPLOITATION OF CYCLOSTATIONARITY FOR SIGNAL-PARAMETER ESTIMATION AND SYSTEM IDENTIFICATION Semiannual Report, 1 Jan. - 30 Jun. 1993
William A. Gardner 30 Jun. 1993 3 p
(Contract N00014-92-J-1218)
(AD-A267137) Avail: CASI HC A01/MF A01

There are three particularly notable accomplishments during the present reporting period. The first is the development of a substantial generalization of our SCORE algorithm for blind adaptive spatial filtering to the Programmable Canonical Correlation Analyzer (PCCA) which can exploit any of a number of signal properties to distinguish between signals of interest (to be beamformed on) and signals not of interest (to be nulled out). The second is a new algorithm for blind adaptive channel equalization for PAM and digital QAM signals and for either single or multiple channels. The third notable achievement is the completion of the edited volume 'Cyclostationarity in Communications and Signal Processing.' DTIC

SEGMENT-BASED ACOUSTIC MODELS FOR CONTINUOUS SPEECH RECOGNITION Progress Report, Apr. - Jun. 1993
Mari Ostendorf and J. R. Rohlicek 8 Jul. 1993 15 p
(Contract N00014-92-J-1778)
(AD-A267138) Avail: CASI HC A03/MF A01

This research aims to develop new and more accurate stochastic models for speaker-independent continuous speech recognition, by extending previous work in segment-based modeling and by introducing a new hierarchical approach to representing intra-utterance statistical dependencies. These techniques, which are more costly than traditional approaches because of the large search space associated with higher order models, are made feasible through rescoring a set of HMM-generated N-best sentence hypotheses. We expect these different modeling techniques to result in improved recognition performance over that achieved by current systems, which handle only frame-based observations and assume that these observations are independent given an underlying state sequence. In the fourth quarter of the project, we have completed the following: (1) ported our recognition system to the Wall Street Journal task, a standard task in the ARPA community; (2) developed an initial dependency-tree model of intra-utterance observation correlation; and (3) implemented baseline language model estimation software. Our initial results on the Wall Street Journal task are quite good and represent significantly improved performance over most HMM systems reporting on the Nov. 1992 5k vocabulary test set. DTIC

OPERATION OF DIGITAL SYSTEMS IN SEVERE ELECTROMAGNETIC ENVIRONMENTS Final Report
K. R. Kowalczyk 11 Jun. 1993 40 p
(AD-A267176; NUWC-NL-TD-10345) Avail: CASI HC A03/MF A01

New digital communication between units is desired in the modernization of a system. Two units of an existing system are linked by circuitry that supplies direct current power, and the connecting wires have been selected for conversion to digital use. This wiring is located within a large bank of alternating current power cables and runs parallel to these cables for several hundred feet. The direct current system realizes no interference from this physical configuration; however, the power wiring radiates electromagnetic fields sufficient to couple noise voltage into a digital system. This project quantifies the effects of high levels of low frequency electromagnetic fields on standard digital communications wiring so that a sufficiently immune circuit configuration can be selected for any applications. A model of the expected electromagnetic environment is presented, and wiretermination voltage measurements are made under varying field and impedance conditions. Standard digital communication design is then examined for compatibility with this environment. DTIC

An adaptive signal canceller is provided in which an adaptive filter effectively tracks any varying gain in the like-polar and cross-polar radar signals and compensates in response to the gain, such that in the event of a disturbance in the orthogonal signal channel, such a disturbance will appear in the output even if it does not exceed the like-polar signal in amplitude. Thus, the system of the invention enhances differences between polarizations and reduces effects common to both polarizations. This has a direct application to the enhancement and detection of a target which reflects incident signals from one polarization to another. The adaptive interference canceller includes the following: an adaptive filter with self-adjusting impulse response for filtering the second orthogonal polarized signal and in response generating an adaptive weighted version of the second signal; and circuitry for subtracting the adaptive weighted second signal from the first polarized signal and in response generating an output signal corresponding to the first polarized signal with the interference component cancelled from it. The resulting output has a high target to clutter ratio and therefore an increased probability of detection. The adaptive filter operates on baseband log video signals of the like-polar and cross-polar channels. Author (CISTI)

HIGHER ORDER STATISTICS IN SIGNAL PROCESSING [BRUK AV HOEYERE ORDENS STATISTIKK I SIGNALBEHANDLING]
Trond Jenserud 10 Nov. 1992 14 p In NORWEGIAN
(FFI-92/2008; ETN-93-94450) Avail: CASI HC A03/MF A01

A new class of signal processing tools was recently developed to the point of practical application. Known as higher order statistics, these tools are beginning to find applicability in many diverse fields; for example sonar, radar biomedicine, seismic data processing, image reconstruction, harmonic retrieval, time delay estimation, adaptive filtering, array processing, and blind equalization. Higher order statistics are useful in problems where either nonGaussianity, nonminimum phase, colored noise, or nonlinearities are important and must be accounted for. An overview of higher order statistics is presented. Some applications where these methods may be of potential value are mentioned. ESA

This paper describes an application of the method of moments to determine resonant frequencies of irregularly shaped microstrip patches embedded in a grounded dielectric slab. For analysis, the microstrip patch is assumed to be excited by a linearly polarized plane wave that is normal to the patch. The surface-current density that is induced on the patch because of the incident field is expressed in terms of subdomain functions by dividing the patch into identical rectangular subdomains. The amplitudes of the subdomain functions, as a function of frequency, are determined using the electric-field integral equation (EFIE) approach in conjunction with the method of moments. The resonant frequencies of the patch are then obtained by selecting the frequency at which the amplitude of the surface-current density is real. The resonant frequencies of the equilateral triangular and other nonrectangular patches are computed using the present technique, and these frequencies are compared with measurements and other independent calculations. (Grant AF-AFOSR-0164-90)
(AD-A267184; AFOSR-93-0514TR) Avail: CASI HC A02/MF A01

This research includes the development and analysis of signal processing estimation algorithms. The main areas of application are sensor array processing for source localization, adaptive signal processing, system identification, and estimation. In the sensor array processing area, we developed algorithms for source localization with decentralized array processing, sensor localization, passive range and bearing estimation, and source localization in multipath and short data applications. We introduced statistical tools that were used to provide compact expressions of the asymptotic variances of source localization algorithms and to obtain, for the first time, concrete analytical performance comparisons. Performance bounds of the Cramer-Rao type were found and used to analyze statistical efficiency. We introduced the use of electromagnetic and acoustic vector sensors for passive source localization and for active target localization and identification. We derived performance bounds and investigated the potential advantages of methods using vector sensors. Simple algorithms for estimating source direction with a vector sensor were proposed along with their statistical performance analysis. In the adaptive signal processing and system identification area we developed algorithms for root factorization and nonlinear filtering. We analyzed the tracking properties of our previously introduced adaptive notch filter for nonstationary signals. DTIC

This is a brief summary of the science findings of the Magellan mission, principally based on data from the radar system. Future plans for Magellan include acquisition of high resolution gravity data from a nearly circular orbit and atmospheric drag and occultation experiments. The Magellan science results represent the combined effort of more than 100 Magellan investigators and their students and colleagues. More extensive discussions

can be found in the August and October, 1992 issues of the Journal of Geophysical Research, Planets. The Magellan mission's scientific objectives were to provide a global characterization of landforms and tectonic features; to distinguish and understand impact processes; to define and explain erosion, deposition, and chemical processes; and to model the interior density distribution. All but the last objective, which requires new global gravity data, have been accomplished, or we have acquired the data that are required to accomplish them. Author (revised)

SPACEBORNE IMAGING RADAR-C INSTRUMENT
Bryan L. Huneycutt *In its* Proceedings of the Third Spaceborne Imaging Radar Symposium 28 May 1993 p 61-65 (For primary document see N94-15886 03-32)
Avail: CASI HC A01/MF A04

The Spaceborne Imaging Radar-C is the next radar in the series of spaceborne radar experiments, which began with Seasat and continued with SIR-A and SIR-B. The SIR-C instrument has been designed to obtain simultaneous multifrequency and simultaneous multipolarization radar images from a low earth orbit. It is a multiparameter imaging radar that will be flown during at least two different seasons. The instrument operates in the squint alignment mode, the extended aperture mode, the scansar mode, and the interferometry mode. The instrument uses engineering techniques such as beam nulling for echo tracking, pulse repetition frequency hopping for Doppler centroid tracking, generating the frequency step chirp for radar parameter flexibility, block floating-point quantizing for data rate compression, and elevation beamwidth broadening for increasing the swath illumination. X-SAR: THE X-BAND SYNTHETIC APERTURE RADAR ON BOARD THE SPACE SHUTTLE
Marian U. Werner *In* JPL, Proceedings of the Third Spaceborne Imaging Radar Symposium 28 May 1993 p 67-73 (For primary document see N94-15886 03-32)
Avail: CASI HC A02/MF A04

The X-band synthetic aperture radar (X-SAR) is the German/Italian contribution to the NASA/JPL Shuttle Radar Lab missions as part of the preparation for the Earth Observation System (EOS) program. The Shuttle Radar Lab is a combination of several radars: an L-band (1.2 GHz) and a C-band (5.3 GHz) multipolarization SAR known as SIR-C (Shuttle Imaging Radar); and an X-band (9.6 GHz) vertically polarized SAR which will be operated synchronously over the same target areas to deliver calibrated multifrequency and multipolarization SAR data at multiple incidence angles from space. A joint German/Italian project office at DARA (German Space Agency) is responsible for the management of the X-SAR project. The space hardware has been developed and manufactured under industrial contract by Dornier and Alenia Spazio. Besides supporting all the technical and scientific tasks, DLR, in cooperation with ASI (Agencia Spaziale Italiano) is responsible for mission operation, calibration, and high precision SAR processing. In addition, DLR developed an airborne X-band SAR to support the experimenters with campaigns to prepare for the missions. The main advantage of adding a shorter wavelength (3 cm) radar to the SIR-C radars is the X-band radar's weaker penetration into vegetation and soil and its high sensitivity to surface roughness and associated phenomena. The performance of each of the three radars is comparable with respect to radiometric and geometric resolution. Author (revised)

Work on the RADARSAT system is progressing towards the currently scheduled launch date of early 1995. The spacecraft bus and the Synthetic Aperture Radar (SAR) payload are at various stages of development. Requirements for the ground segment have been mostly established. The design of the ground elements such as the mission control facility and the SAR data processor is underway. The SAR applications development work is continuing and the chosen distributor, RADARSAT International Inc. (RSI) is making preparations to market RADARSAT data internationally. A plan for the follow-on to RADARSAT 1 is being finalized to ensure continuity of SAR data under the Radarsat program. Author (revised)

The results of a conceptual design study and the performance of key components of the Bread Board Model (BBM) of the Tropical Rainfall Measuring Mission (TRMM) radar are presented. The radar, which operates at 13.8 GHz and is designed to meet TRMM mission objectives, has a minimum measurable rain rate of 0.5 mm/h with a range resolution of 250 m, a horizontal resolution of about 4 km, and a swath width of 220 km. A 128-element active phased array system is adopted to achieve contiguous scanning within the swath. The basic characteristics of BBM were confirmed by experiments. The development of EM started with the cooperation of NASDA and CRL. Author (revised)

The data needs in scientific hydrology involve measurements of system states and fluxes. The microwave region is particularly well suited for measuring the system states of soil moisture and snow and the major flux into the earth as rainfall. This paper discusses the unique data needs of hydrology and presents some recent examples from AIRSAR experiments.

Regional air pollution, land-use conversion, and projected climate change all affect ecosystem processes at large scales. Changes in vegetation cover and growth dynamics can impact the functioning of ecosystems, carbon fluxes, and climate. As a result, there is a need to assess and monitor vegetation structure and function comprehensively at regional to global scales. To provide a test of our present understanding of how ecosystems operate at large scales we can compare model predictions of CO2, O2, and methane exchange with the atmosphere against regional measurements of interannual variation in the atmospheric concentration of these gases. Recent advances in remote sensing of the Earth's surface are beginning to provide methods for estimating important ecosystem variables at large scales. Ecologists attempting to generalize across landscapes have made extensive use of models and remote sensing technology. The success of such ventures is dependent on merging insights and expertise from two distinct fields. Ecologists must provide the understanding of how well models emulate important biological variables and their interactions; experts in remote sensing must provide the biophysical interpretation of complex optical reflectance and radar backscatter data.

On a global scale, forests represent most of the terrestrial standing biomass (80 to 90 percent). Thus, natural and anthropogenic change in forest covers can have major impacts not only on local ecosystems but also on global hydrologic, climatic, and biogeochemical cycles that involve exchange of energy, water, carbon, and other elements between the earth and atmosphere. Quantitative information on the state and dynamics of forest ecosystems and their interactions with the global cycles appear necessary to understand how the earth works as a natural system. The information required includes the lateral and vertical distribution of forest cover, the estimates of standing biomass (woody and foliar volume), the phenological and environmental variations and disturbances (clearcutting, fires, flood), and the longer term variations following deforestation (regeneration, successional stages). To this end, seasonal, annual, and decadal information is necessary in order to separate the long term effects in the global ecosystem from short term seasonal and interannual variations. Optical remote sensing has been used until now to study the forest cover at local, regional, and global scales. Radar remote sensing, which provides recent SAR data from space on a regular basis, represents an unique means of consistently monitoring different time scales, at all latitudes and in any atmospheric conditions. Also, SAR data have shown the potential to detect several forest parameters that cannot be inferred from optical data. The differences--and complementarity--lie in the penetration capabilities of SAR data and their sensitivity to dielectric and geometric properties of the canopy volume, whereas optical data are sensitive to the chemical composition of the external foliar layer of the vegetation canopy.

This document contains a number of viewgraphs on surface and vegetation backscattering. A classification of vegetation based on general scattering properties is presented. Radar scattering mechanisms are discussed, and backscattering and reflection coefficients for soil back scattering models are given. Radar response to vegetation is presented, with the objectives to discriminate and classify vegetation; to estimate biomass, leaf area index (LAI), and soil moisture; and to monitor changes, including deforestation and growth. Both theory and observation (laboratory, field, air SAR, and European Remote Sensing Satellite (ERS-1) observations) are used to present backscatter coefficients and other data for various vegetation types. ERS-1 results include class statistics, comparison with theory, and biomass response and seasonal variation (LAI) for deciduous and coniferous forests.

In this paper we applied Cloude's decomposition to imaging radar polarimetry. We show in detail how the decomposition results can guide the interpretation of scattering from vegetated areas. For multifrequency polarimetric radar measurements of a clear-cut area, the decomposition leads us to conclude that the vegetation is probably thin compared to even the C-band radar wavelength of 6 cm. For a frosted area, we notice an increased amount of even number of reflection scattering at P-band and L-band, probably the result of penetration through the coniferous canopy resulting in trunk-ground double reflection scattering. However, the scattering for the forested area is still dominated by scattering from randomly oriented cylinders. It is found that these cylinders are thicker than in the case of clear-cut areas, leading us to conclude that scattering from the branches probably dominates in this case.

Analyses of synthetic aperture radar (SAR) image data were performed at DLR to classify various kinds of vegetation and different terrain types. The data were collected both with the DLR experimental synthetic aperture radar (E-SAR) in X-band, C-band, and L-band and with the NASA/JPL DC-8 SAR in C-band, L-band, and P-band. E-SAR is a single frequency and single polarization system (both parameters can be selected) but several flights were used to collect multifrequency/multipolarization data which were geometrically matched after processing. Classification of different crop types was based on comparison of the backscatter coefficients of calibrated SAR data in different frequency bands and polarizations. The DC-8 STAR collects polarimetric data in different bands simultaneously. Data acquired with the NASA/JPL DC-8 STAR are qualified for scientific investigations by reducing the cross-talk and channel imbalance to a tolerable extent. The data are absolutely calibrated by using reference targets with known backscattering cross-sections. The signatures and polarimetric features of terrain types, such as grassland, concrete, sea, forest (coniferous; deciduous) and urban areas, are extracted and discussed with respect to frequency and incidence angle dependence. A multifrequency polarimetric feature vector was applied for classification. The results of this new approach for separating and classifying different object classes are presented.

The release of latent heat of condensation is the largest internal energy source of the atmosphere. Latent heating is most significant during the precipitation process. Our knowledge of the distribution of precipitation is poor. It is only well observed within limited areas of the globe. Over the oceans, for example, it is known only to within a factor of two. Thus, there are strong scientific requirements for observations of precipitation from instruments on board a satellite. The Tropical Rainfall Measuring Mission (TRMM) will be the first satellite to measure rainfall with adequate accuracy and provide information about the vertical distribution of precipitation, not only in tropics and subtropics, but to plus or minus 35 degrees of latitude. There is a need for the continuity of rain observations for climate modeling purposes and to expand observations to cover more of the globe than simply plus or minus 35 degrees latitude.

Because of the needs of future projects like ENVISAT and the experiences made with the current operational ERS-1 facilities, a radical change in the synthetic aperture radar (SAR) processing scenarios can be predicted for the next years. At the German PAF several new developments were initialized which are driven mainly either by user needs or by system and operational constraints ('lessons learned'). At the end there will be a major simplification and uniformation of all used computer systems. Especially the following changes are likely to be implemented at the German PAF: transcription before archiving, processing of all standard products with high throughput directly at the receiving stations, processing of special

'high-valued' products at the PAF, usage of a single type of processor hardware, implementation of a large and fast on-line data archive, and improved and unified fast data network between the processing and archiving facilities. A short description of the current operational SAR facilities as well as the future implementations are given. Author (revised)

Single and multi-frequency antenna concepts were developed to evaluate the feasibility of building large aperture polarimetric synthetic aperture radar (SAR) systems to be launched in low cost vehicles such as the Delta 2. The antennas are 18.9 m long by 2.6 m wide (L-band) and achieve single polarization imaging to an incidence angle of 55 degrees and dual/quad imaging to 42 degrees. When combined with strawman spacecraft designs, both concepts meet the mass and volume constraints imposed by a Delta 2 launch. Author (revised)

The Synthetic Aperture Radar (SAR) has viewed, in the last two years, a huge increment of interest from many preset and potential users. The good spatial resolution associated to the all weather capability lead to considering SAR not only a scientific instrument but a tool for verifying and controlling the daily human relationships with the Earth Environment. New missions were identified for SAR as spatial resolution became lower than three meters: disasters, pollution, ships traffic, volcanic eruptions, earthquake effect are only a few of the possible objects which can be effectively detected, controlled and monitored by SAR mounted on satellites. High resolution radar design constraints and dimensioning are discussed. Author (revised)

A SUMMARY OF MICROWAVE REMOTE SENSING INVESTIGATIONS PLANNED FOR BOREAS **c43**
Kyle C. McDonald *In its* Proceedings of the Third Spaceborne Imaging Radar Symposium 28 May 1993 p 415-416 Sponsored in part by Energy, Mines and Resources Canada (For primary document see N94-15886 03-32)
Avail: CASI HC A01/MF A04

The Boreal Ecosystem - Atmosphere Study (BOREAS) is a multidisciplinary field and remote sensing study that will be implemented jointly by the United States and Canada. The goal of BOREAS is to obtain an improved understanding of the interactions between the boreal forest biome and the atmosphere in order to clarify their roles in global change. Specific objectives are to improve the understanding of the processes that govern the exchanges of water, energy, heat, carbon, and trace gases between boreal ecosystems and the atmosphere, and to develop and validate remote sensing algorithms for transferring the understanding of these processes from local to regional scales. Two principal field sites, both within Canada, were selected. The northern site is located near Thompson, Manitoba, and the southern site encompasses Prince Albert National Park in Saskatchewan. The growing season in the northern site tends to be limited by growing-degree days while the southern site is limited by soil moisture and fire frequency. Most of the field work will occur at these two sites during 1993 and 1994 as part of six field campaigns. The first of these campaigns is scheduled for August 1993 and will involve instrument installation and an operational shakedown. Three large scale Intensive Field Campaigns (IFC's) are scheduled for 1994, along with two smaller scale Focused Field Campaigns (FFC's). The first 1994 campaign will be an FFC designed to capture the biome under completely frozen conditions during the winter. The second FFC and the first IFC are scheduled to capture the spring thaw period. Another IFC will take place in the summer during a period of maximum water stress. Finally, the third FFC will be scheduled to capture the collapse into senescence during the fall. Author (revised)

Canadian Satellite Communications (Cancom) has as its core business the provision of television and radio signals to cable systems in Canada, with the objective of making affordable broadcast signals available to remote and/or small communities. Cancom also provides direct-to-home services to backyard receiving dishes, as well as satellite digital data business communications services, satellite business television, and satellite network services. Its business communication services range from satellite links for big-city businesses with small branch operations located far from major centers, to a mobile messaging and tracking system for the trucking industry. Revenues in 1992 totalled $48,212,000 and net income was just over $7 million. Cancom bought 10 percent interest in Leosat Corp. of Washington, DC, who are seeking approval to operate a position locator network from low-orbit satellites. Cancom has also become a partner in SovCan Star Satellite Communications Inc., which will build an international satellite system in partnership with Russia. The first satellite in this east-west business network will be placed in a Russian orbital slot over the Atlantic by 1996, and a second satellite will follow for the Pacific region. This annual report of Cancom's activities for 1992 includes financial statements and a six year financial review. CISTI

DUAL POLARIZATION MICROSTRIP ARRAY ANTENNA Patent
Adrian W. Alden, inventor (to Micromedia Ltd.) and Tom T. Ohno, inventor (to Micromedia Ltd.) 22 Sep. 1992 23 p
(CA-Patent-1-307-842; Int-Patent-Class-H01R-21/26; Int-Patent-Class-H01R-13/08; CTN-93-60779) Copyright Avail: Issuing Activity (Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC)

A dual polarized microstrip array antenna is provided for power reception or transmission of electromagnetic waves. The antenna has a plurality of symmetrically arranged identical antenna units. Each unit comprises a patch antenna element of given length and a plurality of identical feedlines, each of which is symmetrically attached to the patch antenna element and has identical microstrip filters, a terminal for an antenna feed, and identical microstrip matching stubs for shorting the transmission line waves at the fundamental and second harmonic. The array antenna further comprises a dielectric layer of a predetermined thickness on one side of which the plurality of the identical antenna units are arranged symmetrically in an array by direct current connecting appropriate feedlines of adjacent antenna units and a common ground plane provided on the other side of the dielectric layer. The antenna of the invention removes difficulties associated with other types of microstrip antennas and increases the overall dual polarization power conversion efficiency by a specific choice of rectenna format and dimensions. PROCEEDINGS OF THE FIFTEENTH NASA PROPAGATION EXPERIMENTERS MEETING (NAPEX 15) AND THE ADVANCED COMMUNICATIONS TECHNOLOGY SATELLITE (ACTS) PROPAGATION STUDIES MINIWORKSHOP
Faramaz Davarian, ed. 1 Jul. 1991 275 p Miniworkshop held in London, Ontario, 28-29 Jun. 1991
(Contract NAS7-918)
(NASA-CR-194539; JPL-Publ-91-31; NAS 1.26:194539) Avail: CASI HC A12/MF A03

The NASA Propagation Experimenters Meeting (NAPEX), supported by the NASA Propagation Program, is convened annually to discuss studies made on radio wave propagation by investigators from domestic and international organizations. The meeting was organized into three technical sessions. The first session was dedicated to Olympus and ACTS studies and experiments, the second session was focused on the propagation studies and measurements, and the third session covered computer-based propagation model development. In total, sixteen technical papers and some informal contributions were presented. Following NAPEX 15, the Advanced Communications Technology Satellite (ACTS) miniworkshop was held on 29 Jun. 1991, to review ACTS propagation activities, with emphasis on ACTS hardware development and experiment planning. Five papers were presented. For individual titles, see N94-16036 through N94-16051.

A REVIEW OF OPEX ACTIVITIES AND MEASUREMENT RESULTS
B. Arbesser-Rastburg *In* JPL, Proceedings of the Fifteenth NASA

Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 12-19 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

A summary is given of the measurements carried out in the framework of OPEX (OLYMPUS Propagation Experimenters Group). In particular, the progress since mid-1990 is presented. In this period two OPEX meetings were held, OPEX 14 (Oct. 1990) and OPEX 15 (Apr. 1991). The First OPEX Workshop was held at ESTEC on 23-24 April 1991.

OLYMPUS PROPAGATION MEASUREMENT RESULTS AT VIRGINIA TECH
Warren Stutzman *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 20-27 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

Virginia Tech is performing a comprehensive set of propagation measurements using the OLYMPUS satellite beacons at 12.5, 20, and 30 GHz. A second 20 GHz diversity terminal is portable and is moved to various spacings up to 50 m away from the fixed 20 GHz terminal. Total power radiometers are also included in each terminal. Radiometer data are used both to set the absolute level of the beacon data and to predict path attenuation. This paper presents initial results from the experiment set.

DATA ACQUISITION, PREPROCESSING AND ANALYSIS FOR THE VIRGINIA TECH OLYMPUS EXPERIMENT
P. Will Remaklus *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 28-35 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

Virginia Tech is conducting a slant path propagation experiment using the 12, 20, and 30 GHz OLYMPUS beacons. Beacon signal measurements are made using separate terminals for each frequency. In addition, short baseline diversity measurements are collected through a mobile 20 GHz terminal. Data collection is performed with a custom data acquisition and control system. Raw data are preprocessed to remove equipment biases and discontinuities prior to analysis. Preprocessed data are then statistically analyzed to investigate parameters such as frequency scaling, fade slope and duration, and scintillation intensity.

THE ACTS PROPAGATION PROGRAM
Dayamoy Chakraborty and Faramaz Davarian *In its* Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 50-54 (For primary document see N94-16035 03-32)
Avail: CASI HC A01/MF A03

The purpose of the Advanced Communications Technology Satellite (ACTS) is to demonstrate the feasibility of the Ka-band (20 and 30 GHz) spectrum for satellite communications, as well as to help maintain U.S. leadership in satellite communications. ACTS incorporates such innovative schemes as time division multiple access (TDMA), microwave and baseband switching, onboard regeneration, and adaptive application of coding during rain-fade conditions. The success or failure of the ACTS experiment will depend on how accurately the rain-fade statistics and fade dynamics can be predicted in order to derive an appropriate algorithm that will combat weather vagaries, specifically for links with small terminals, such as very small aperture terminals (VSAT's) where the power margin is a premium. This article describes the planning process and hardware development program that will comply with the recommendations of the ACTS propagation study groups.

PROPAGATION MEASUREMENTS IN ALASKA USING ACTS BEACONS
Charles E. Mayer *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 55-60 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

The placement of an ACTS propagation terminal in Alaska has several distinct advantages. First is the inclusion of a new and important climatic zone to the global propagation model. Second is the low elevation look angle from Alaska to ACTS. These two unique opportunities also present problems unique to the location, such as extreme temperatures and lower power levels. These problems are examined and compensatory solutions are presented.

PLANNED LMSS PROPAGATION EXPERIMENT USING ACTS: PRELIMINARY ANTENNA POINTING RESULTS DURING MOBILE OPERATIONS
John R. Rowland, Julius Goldhirsh, Wolfhard J. Vogel (Texas Univ., Austin.), and Geoffrey W. Torrence (Texas Univ., Austin.) *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 61-72 (For primary document see N94-16035 03-32)
(Contracts JPL-956520; N00039-89-C-0001)
Avail: CASI HC A03/MF A03

An overview and a status description of the planned LMSS mobile K band experiment with ACTS is presented. As a precursor to the ACTS mobile measurements at 20.185 GHz, measurements at 19.77 GHz employing the Olympus satellite were originally planned. However, because of the demise of Olympus in June of 1991, the efforts described here are focused towards the ACTS measurements. In particular, we describe the design and testing results of a gyro controlled mobile-antenna pointing system. Preliminary pointing measurements during mobile operations indicate that the present system is suitable for measurements employing a 15 cm aperture (beamwidth at approximately 7 deg) receiving antenna operating with ACTS in the high gain transponder mode. This should enable measurements with pattern losses smaller than plus or minus 1 dB over more than 95 percent of the driving distance. Measurements with the present mount system employing a 60 cm aperture (beamwidth at approximately 1.7 deg) results in pattern losses smaller than plus or minus 3 dB for 70 percent of the driving distance. Acceptable propagation measurements may still be made with this system by employing developed software to flag out bad data points due to extreme pointing errors. The receiver system including associated computer control software has been designed and assembled. Plans are underway to integrate the antenna mount with the receiver on the University of Texas mobile receiving van and repeat the pointing tests on highways employing a recently designed radome system.

PROPAGATION-RELATED AMT DESIGN ASPECTS AND SUPPORTING EXPERIMENTS
Khaled Dessouky and Polly Estabrook *In its* Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 73-80 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

The ACTS Mobile Terminal (AMT) is presently being developed with the goal of significantly extending commercial satellite applications and their user base. A thorough knowledge of the Ka-band channel characteristics is essential to the proper design of a commercially viable system that efficiently utilizes the valuable resources. To date, only limited tests have been performed to characterize the Ka-band channel, and they have focused on the needs of fixed terminals. As part of the value of the AMT as a Ka-band test bed is its function as a vehicle through which tests specifically applicable to the mobile satellite communications can be performed. The exact propagation environment with the proper set of elevation angles, vehicle antenna gains and patterns, roadside shadowing, rain, and Doppler is encountered. The ability to measure all of the above, as well as correlate

their effects with observed communication system performance, creates an invaluable opportunity to understand in depth Ka-band's potential in supporting mobile and personal communications. This paper discusses the propagation information required for system design, the setup with ACTS that will enable obtaining this information, and finally the types of experiments to be performed and data to be gathered by the AMT to meet this objective. SATELLITE SOUND BROADCAST PROPAGATION MEASUREMENTS

Wolfhard J. Vogel and Geoffrey W. Torrence *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Progagation Studies Miniworkshop 1 Jul. 1991 p 123-131 (For primary document see N94-16035 03-32)

Avail: CASI HC A02/MF A03

Power transmitted from atop a 17.9 m tower in simulation of a satellite signal, emitted by a tone generator sweeping from 700 to 1800 MHz, was received using a 90 deg beamwidth linearly scanning antenna at many locations inside six buildings of solid brick, corrugated sheet-metal, wood-frame, mobile home, and concrete wall construction. The signal levels are found to have much structure in the spatial and frequency domain but were relatively stable in time. Typically, people moving nearby produced less than 0.5 dB variations, whereas a person blocking the transmission path produces 6 to 10 dB fades. Losses, which at an average position in a room increased from 6 to 12 dB over 750 to 1750 MHz, could be mitigated to 2 to 6 dB by moving the antenna typically less than 30 cm. Severe losses (17.5 dB, mitigated to 12.5 dB) were observed in a concrete wall building, which also exhibited the longest multipath delays (greater than 100 ns). Losses inside a mobile home were even larger (greater than 20 dB) and independent of antenna orientation. The losses showed a clear frequency dependence. Author (revised)

AN OVERVIEW OF THE TEXT PROPAGATION EFFECTS FOR LAND-MOBILE-SATELLITE SYSTEMS: EXPERIMENTAL AND MODELING RESULTS

Julius Goldhirsh and Wolfhard J. Vogel (Texas Univ., Austin.) *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 132-139 (For primary document see N94-16035 03-32)

(Contracts JPL-956520; N00039-89-C-0001)

Avail: CASI HC A02/MF A03

We present an overview of the contents of the text having the above title and which is now in the form of a preliminary document titled, 'Propagation Handbook for Land-Mobile-Satellite Systems-Preliminary.' At this writing the text is undergoing peer review, and the final revised manuscript will be published in the near future as a NASA document. The text was inspired by a series of Land-Mobile-Satellite System (LMSS) experiments by the authors and other investigators at UHF and L-Band. The rationale for its writing is to place in a single document an overview of the previous propagation related salient experimental and modeling results pertaining to LMSS scenarios. It is apparent that LMSS propagation at UHF and L-Band can be seriously degraded because of attenuation (e.g., greater than 10 dB) caused by roadside tree shadowing. The extent of attenuation is shown to depend on such factors at the elevation angle to the satellite, the bearing of the line-of-signt path to the satellite relative to the line of roadside trees, the side of the road in which the vehicle is driven, the season, and the frequency. Multipath effects during line-of-sight communications are shown to cause less serious fading (e.g., smaller than 3 dB for 90 percent of the driving distance). Author (revised)

DATABASE FOR PROPAGATION MODELS

Anil V. Kantak *In its* Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 147-158 (For primary document see N94-16035 03-32)

Avail: CASI HC A03/MF A03

A propagation researcher or a systems engineer who intends to use the results of a propagation experiment is generally faced with various database tasks such as the selection of the computer software, the hardware, and the writing of the programs to pass the data through the models of interest. This task is repeated every time a new experiment is conducted or the same experiment is carried out at a different location generating different data. Thus the users of this data have to spend a considerable portion of their time learning how to implement the computer hardware and the software towards the desired end. This situation may be facilitated considerably if an easily accessible propagation database is created that

has all the accepted (standardized) propagation phenomena models approved by the propagation research community. Also, the handling of data will become easier for the user. Such a database construction can only stimulate the growth of the propagation research it if is available to all the researchers, so that the results of the experiment conducted by one researcher can be examined independently by another, without different hardware and software being used. The database may be made flexible so that the researchers need not be confined only to the contents of the database. Another way in which the database may help the researchers is by the fact that they will not have to document the software and hardware tools used in their research since the propagation research community will know the database already. The following sections show a possible database construction, as well as properties of the database for the propagation research. Author (revised)

A CCIR-BASED PREDICTION MODEL FOR EARTH-SPACE PROPAGATION
Zengjun Zhang and Ernest K. Smith *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 159-172 (For primary document see N94-16035 03-32)
Avail: CASI HC A03/MF A03

At present there is no single 'best way' to predict propagation impairments to an Earth-Space path. However, there is an internationally accepted way, namely that given in the most recent version of CCIR Report 564 of Study Group 5. This paper treats a computer code conforming as far as possible to Report 564. It was prepared for an IBM PS/2 using a 386 chip and for Macintosh SE or Mach II. It is designed to be easy to write and read, easy to modify, fast, have strong graphic capability, contain adequate functions, have dialog capability and windows capability. Computer languages considered included the following: (1) Turbo BASIC, (2) Turbo PASCAL, (3) FORTRAN, (4) SMALL TALK, (5) C++, (6) MS SPREADSHEET, (7) MS Excel-Macro, (8) SIMSCRIPT II.5, and (9) WINGZ. A STUDY OF LAND MOBILE SATELLITE SERVICE MULTIPATH EFFECTS USING SATLAB SOFTWARE
Richard L. Campbell *In* JPL, Proceedings of the Fifteenth NASA Propagation Experimenters Meeting (NAPEX 15) and the Advanced Communications Technology Satellite (ACTS) Propagation Studies Miniworkshop 1 Jul. 1991 p 176-185 (For primary document see N94-16035 03-32)
Avail: CASI HC A02/MF A03

A software package is proposed that uses the known properties of signals received in multipath environments along with the mathematical relationships between signal characteristics to explore the effects of antenna pattern, vehicle velocity, shadowing of the direct wave, distributions of scatters around the moving vehicle and levels of scattered signals on the received complex envelope, fade rates and fade duration, Doppler spectrum, signal arrival angle spectrum, and spatial correlation. The data base may be either actual measured received signals entered as ASCII flat files or data synthesized using a built in model. An example illustrates the effect of using different antennas to receive signals in the same environment. Author (revised)

A RAY TRACE MODEL FOR PROPAGATION LOSS Final Report
C. P. Hattan Feb. 1993 66 p
(AD-A266314; NCCOSC/RDT/E-TR-1576) Avail: CASI HC A04/MF A01

This study was conducted to determine the feasibility of replacing the optical-region propagation model currently assessing the effect of lower atmosphere refraction on electromagnetic (EM) system performance within the Engineer's Refractive Effects Prediction System (EREPS) with a complete ray trace model. The ray trace model uses a full ray trace solution to describe the propagation environment. It is implemented in a Microsoft QuickBASIC program intended for IBM-compatible personal computers. The ray trace model can determine propagation loss under certain conditions, but it resolves ray paths with increasing difficulty when the EM system frequency rises, and it produces large divergence factors. Since attempts to eliminate fluctuations in the ray trace divergence factors have failed, the study's results argue that the ray trace model is not suitable for EREPS. DTIC

(Grant NAG5-557)
Avail: CASI HC A03/MF A01

In his seminal 1948 paper 'The Mathematical Theory of Communication,' Claude E. Shannon derived the 'channel coding theorem' which has an explicit upper bound, called the channel capacity, on the rate at which 'information' could be transmitted reliably on a given communication channel. Shannon's result was an existence theorem and did not give specific codes to achieve the bound. Some skeptics have claimed that the dramatic performance improvements predicted by Shannon are not achievable in practice. The advances made in the area of coded modulation in the past decade have made communications engineers optimistic about the possibility of achieving or at least coming close to channel capacity. Here we consider the possibility in the light of current research results. Author (revised)

A SIMULATION STUDY OF THE PERFORMANCE OF THE NASA (2,1,6) CONVOLUTIONAL CODE ON RFI/BURST CHANNELS
Lance C. Perez and Daniel J. Costello, Jr. *In its* Low-Complexity, High-Performance Bandwidth Efficient Coding and Coded Modulation

Techniques for Satellite and Space Communications Nov. 1993 13 p (For primary document see N94-16506 03-32)
(Grants NAG5-557; NGT-70109)
Avail: CASI HC A03/MF A01

In an earlier report, the LINKABIT Corporation studied the performance of the (2,1,6) convolutional code on the radio frequency interference (RFI)/burst channel using analytical methods. Using an R(sub 0) analysis, the report concluded that channel interleaving was essential to achieving reliable performance. In this report, Monte Carlo simulation techniques are used to study the performance of the convolutional code on the RFI/burst channel in more depth. The basic system model under consideration is shown. The convolutional code is the NASA standard code with generators g(exp 1) = 1+D(exp 2)+D(exp 3)+D(exp 5)+D(exp 6) and g(exp 2) = 1+D+D(exp 2)+D(exp 3)+D(exp 6) and d(sub free) = 10. The channel interleaver is of the convolutional or periodic type. The binary output of the channel interleaver is transmitted across the channel using binary phase shift keying (BPSK) modulation. The transmitted symbols are corrupted by an RFI/burst channel consisting of a combination of additive white Gaussian noise (AWGN) and RFI pulses. At the receiver, a soft-decision Viterbi decoder with no quantization and variable truncation length is used to decode the deinterleaved sequence. Author (revised)

SEARCH FOR OPTIMAL DISTANCE SPECTRUM CONVOLUTIONAL CODES
Matthew C. Connor, Lance C. Perez, and Daniel J. Costello, Jr. *In its* Low-Complexity, High-Performance Bandwidth Efficient Coding and Coded Modulation Techniques for Satellite and Space Communications Nov. 1993 20 p Presented at the Fourth Annual Argonne Symposium for Undergraduates in Science, Engineering, and Mathematics, Argonne, IL, 6 Nov. 1993 (For primary document see N94-16506 03-32)
(Grants NAG5-557; NSF NCR-89-03429)
Avail: CASI HC A03/MF A01

In order to communicate reliably and to reduce the required transmitter power, NASA uses coded communication systems on most of their deep space satellites and probes (e.g. Pioneer, Voyager, Galileo, and the TDRSS network). These communication systems use binary convolutional codes. Better codes make the system more reliable and require less transmitter power. However, there are no good construction techniques for convolutional codes. Thus, to find good convolutional codes requires an exhaustive search over the ensemble of all possible codes. In this paper, an efficient convolutional code search algorithm was implemented on an IBM RS6000 Model 580. The combination of algorithm efficiency and computational power enabled us to find, for the first time, the optimal rate 1/2, memory 14, convolutional code. Author

SIGNAL PROCESSING IN IMPULSIVE ELECTROMAGNETIC INTERFERENCE Progress Report
Serena M. Zabin 30 Jun. 1993 7 p
(Contract N00014-91-J-1334)
(AD-A266425) Avail: CASI HC A02/MF A01

Statistical signal processing functions such as signal detection, estimation, and identification play a key role in the development of effective communications, radar, and sonar systems. For example, advanced statistical methods are emerging as being particularly important in digital communications systems operating in channels corrupted by interference from such phenomena as multiple-access noise, intentional jamming, and impulsive noise sources. Conventional demodulation methods, such as coherent matched filtering, often suffer serious performance degradation when subject to interference of these types; however, this degradation can frequently be eliminated through the use of more sophisticated signal processing techniques. During this reporting period, the focus of our work has been on the problem of obtaining optimum and efficient identification and detection procedures for impulsive channels. Of particular interest is the Middleton Class A noise model, which is a widely-accepted statistical-physical model for impulsive interference superimposed on a Gaussian background. The model has two basic parameters that can be adjusted to fit a wide variety of impulsive noise phenomena occurring in practice. DTIC

(NASA-TP-3361; L-17218; NAS 1.60:3361) Avail: CASI HC A03/MF A01

This report describes an application of the method of moments to calculate the electromagnetic scattering from irregularly shaped, thin, metallic flat plates in free space. In the present technique, an irregularly shaped plate is enclosed by a rectangle on which the surface-current density is

then expressed in terms of subdomain functions by dividing the rectangle into subsections. A shape function is introduced to ensure zero current outside the patch. The surface-current density is determined using the electric field integral equation (EFIE) approach in conjunction with the method of moments, and from a knowledge of the surface-current density, the electromagnetic scattering from a plate is calculated. Using this technique, the electromagnetic scattering from a hexagonal plate; an equilateral triangular plate; an equilateral triangular plate with a concentric, equilateral triangular hole and an inverted, equilateral triangular hole; and a diamond-shaped plate is computed and compared with the numerical results obtained by using the Electromagnetic Surface Patch (ESP) code developed by Ohio State University. The numerical results compare favorably with the measurements performed on these shapes in the Langley Experimental Test Range facility. Author (revised)

REDUCING DATA DIMENSION TO LOWER SIGNAL PROCESSING COMPUTATIONAL REQUIREMENTS AND MAXIMIZE PERFORMANCE Final Report, 1 Sep. 1989 - 31 Mar. 1993
Barry D. VanVeen 11 May 1993 5 p
(Contract DAAL03-89-K-0141)
(AD-A266606; ARO-26460.22-EL) Avail: CASI HC A01/MF A01

The problem studied concerns reducing the dimension of data by mapping it through rectangular matrix transformations before application of signal processing algorithms. Our work addressed applications of this principle in adaptive beamforming, spectral estimation, and detection problems. While dimension reduction often leads to dramatic reductions in the computational burden of the signal processing algorithm, it can also introduce significant asymptotic performance losses if the transformation is not chosen properly. We choose dimension reducing transformations to optimize performance criteria associated with the problem of interest. Our results indicate that dramatic reductions in dimension can be achieved with relatively small asymptotic performance losses using these design procedures. Performance analyses demonstrate that dimension reduction is most profitably used in applications where relatively short data records are available or fast response time is required. In these cases dimension reduction actually improves performance. DTIC

ENHANCED DOWN-RANGE PROFILES OF COMPLEX TARGETS USING WIDEBAND RADAR ECHO RETURNS Interim Report, Oct. - Dec. 1992
Brett Borden May 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. BR0-5202)
(AD-A266508; NAWC-WPNS-TP-8124) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Small radar detection and tracking systems--in particular, radar guided missile systems--are of great utility because of their all-weather performance and their long range capabilities. A major drawback with these systems results from the relatively simple data that they collect and the difficulty in using these data for target classification and identification purposes. We propose a technique which employs the statistics of the tracking data used by many missile seekers and which creates a cross-range target structure map that can be expressed as a function of the target's down-range extent. These data consist of ordinary azimuth elevation phase monopulse measurements collected from a small set of (unknown) aspects presented by the target as it maneuvers. The method requires a minimal computational burden and holds the potential to be used for automatic (machine-based) target classification in realistic (time and data limited) environments. DTIC

MANUFACTURING TOLERANCE REQUIREMENTS FOR FREQUENCY SELECTIVE SURFACES M.S. Thesis
Edwin V. Chavez Jun. 1993 232 p
(AD-A266541; AFIT/GE/ENG/93J-01) Avail: CASI HC A11/MF A03

This thesis investigated the change of radome transmission behavior of Frequency Selective Surfaces (FSS), with errors introduced in the slots' geometric parameters. Three FSS's were analyzed. The first is a single thin conducting plane with an array of 35 columns of thin linear slots in free space. The second is composed of two, thin conducting planes with an array of 35 columns of thin linear slots per each FSS in free space. The third consists of two thin conducting planes with an array of 21 columns of thin linear slots per each FSS, embedded in dielectric layers. After designing the ideal FSS with the code known as PMM, Gaussian errors are introduced, on lengths, widths, locations of the slot columns and z locations of reference slots in each column, and using a 'finite by infinite' array code (SFI) the value of the peak transmitted power and the radiation pattern are obtained several times for different generated Gaussian errors. All the results are tabulated and presented in a statistical and graphical way with the purpose of defining tolerance requirements. DTIC

APPLICATIONS AND DEVELOPMENT OF COMMUNICATION MODELS FOR THE TOUCHSTONE GAMMA AND DELTA PROTOTYPES Final Report, 1 Jan. 1992 - 30 Jun. 1993
Steven R. Seidel 16 Aug. 1993 4 p
(Grant NAG2-757)
(NASA-CR-193617; NAS 1.26:193617) Avail: CASI HC A01/MF A01

The goal of this project was to develop models of the interconnection networks of the Intel iPSC/860 and DELTA multicomputers to guide the design of efficient algorithms for interprocessor communication in problems that commonly occur in CFD codes and other applications. Interprocessor communication costs of codes for message-passing architectures such as the iPSC/860 and DELTA significantly affect the level of performance that can be obtained from those machines. This project addressed several

specific problems in the achievement of efficient communication on the Intel iPSC/860 hypercube and DELTA mesh. In particular, an efficient global processor synchronization algorithm was developed for the iPSC/860 and numerous broadcast algorithms were designed for the DELTA.

UNDERSTANDING PARTITIONS AND THE NO PARTITION ASSUMPTION
Aleta Ricciardi, Andre Schiper, and Kenneth Birman Jun. 1993 12 p
(Contract N00014-92-J-1866)
(AD-A266296; TR-93-1355) Avail: CASI HC A03/MF A01

The paper discusses partitions is asynchronous message-passing systems. In such systems slow processes and slow links can lead to virtual partitions that are indistinguishable from real ones. This raises the following question: what is a partition in an asynchronous system? To overcome the impossibility of detecting crashed processes in an asynchronous system, our system model incorporates a failure suspector to detect (possibly erroneously) process failures. Based on failure suspicions we give a definition of partitions that accounts for real partitions as well as virtual ones. We show that under certain assumptions about the process behavior, any incorrect failure suspicion inevitably partitions the system. We then show how to interpret the absence of partition assumption.

MOVING TARGET INDICATOR USING HIGHER ORDER STATISTICS Patent
Robert D. Pierce, inventor (to Navy) 27 Jul. 1993 16 p Filed 30 Sep. 1992
(AD-D015890; US-Patent-5,231,403; US-Patent-Appl-SN-953622) Avail: US Patent and Trademark Office

While the computation of high resolution radar images based on higher order statistics is position insensitive, velocity estimation may be based on the ratios of values of a trispectral slice and a cross-trispectral slice computed as quadruple products of complex valued signals developed by coherent radar. Signal-to-noise ratio is improved by either averaging over a plurality of bursts during computation of both the trispectral slice and the cross-trispectral slice or averaging of values of ratios of trispectral slice and cross-trispectral slice values at particular frequencies or wavenumbers, or both.

HIGH RESOLUTION RADAR PROFILING USING HIGHER-ORDER STATISTICS Patent
Robert D. Pierce, inventor (to Navy) 13 Jul. 1993 14 p Filed 26 Jun. 1992
(AD-D015891; US-Patent-5,227,801; US-Patent-Appl-SN-904927) Avail: US Patent and Trademark Office

A coherent radar is used for achieving high resolution radar imaging of a moving object in sea clutter and noise. A stored replica of the transmitted waveform is combined with the returned signal in a synchronous detector to produce in-phase and quadrature (I and Q or complex) samples. High resolution is achieved by transmitting a series of pulses, each at a different frequency, and then processing these complex samples to produce a synthetic down-range profile. To enhance the radar target or object from system noise and sea clutter, the complex I and Q (in-phase and quadrature component) samples from the radar are coherently averaged in a special two-dimensional slice of the trispectrum (e.g. quadruple product or fourth-order moment). This formulation of the fourth moment retains all important target information and suppresses Gaussian noise. Once averaged, a new set of I and Q samples are reconstructed that produce the same trispectral slice as this average. These reconstructed samples are then transformed using conventional Fourier transform methods to produce the average, or enhanced, down-range profile.

ACOUSTO-OPTICAL CLASSIFIER Patent
Werner G. Hueber, inventor (to Navy) and James L. Jernigan, inventor (to Navy) 6 Oct. 1992 4 p Filed 13 Dec. 1976
(AD-D015894; US-Patent-5,153,597; US-Patent-Appl-SN-752713; US-Patent-Class-342-192) Avail: US Patent and Trademark Office

An acousto-optical classifier for classifying wide bandwidth signals such as high resolution radar returns of ships or very short pulse length signals of radar emitters is presented. This is accomplished by generating the Fourier transform power spectrum with an acousto-optic cell oriented in the Bragg configuration and a low power coherent light source such as a laser. The power spectrum is detected to provide inputs to a digital classifier.

TARGET DETECTION BY WAY OF KALMAN FILTERING M.S. Thesis
Gary A. Sipe Mar. 1993 83 p
(AD-A267314) Avail: CASI HC A05/MF A01

A simple, time domain method is used to analyze moderate to high PRF radar signals. The quantities of interest are the signal's PRF, SNR, and time of arrival. The time of arrival problem is important because it can be used, with multiple sensors, to determine the position of the emitting target. An algorithm is described which will produce these values using Kalman filtering. Individual pulses in a pulsed type radar are measured against a threshold using a two sample detection scheme to provide some glitch rejection. Results of individual time domain measurements of the signal parameter are smoothed with a Kalman filter. Integrating the pulse train envelope during the radar dwell time provides the energy centroid for a scan cycle. This centroid, time differenced with multiple sensors, provides observables for an Extended Kalman Filter for emitter localization. The work here simulates all data. Tests of the algorithms developed were conducted on real, classified data in addition to the work presented here.

FOUR FREQUENCY-SHIFT KEYING (4-FSK) SPREAD SPECTRUM MODULATOR AND DEMODULATOR M.S. Thesis
Terrence J. Murray Mar. 1993 101 p
(AD-A267433) Avail: CASI HC A06/MF A02

This thesis explores the potential use of a four frequency-shift keying (4-FSK), spread spectrum modulator and demodulator (MODEM) in a low orbit satellite. In this first approach, a short maximal length sequence of 127 chips would be used to spread the four frequencies. After successful implementation, the design could be extended to longer codes which would provide for greater processing gain. This MODEM was not preselected for use in satellite communications based on the merits of 4-FSK, but was assigned as one of four possible digital communication designs. A MODEM would be selected for use in the Petite Amateur Navy Satellite after a thorough design review.

(Contract F49620-90-C-0065)
(AD-A267376; AFOSR-93-0484TR) Avail: CASI HC A09/MF A02

An innovative communication system has been developed. This system has the potential for improved secure communication for covert operations. By modulating data on the chaotic signal used to synchronize two nonlinear systems, they have created a Low Probability of Intercept (LPI) communications system. The researchers derived the equations which govern the system, made models of the system, and performed numerical simulations to test these models. The theoretical and numerical studies of this system have been validated by experiment. A recent design improvement has led to a system that synchronizes at 0 db Signal-to-Noise. This development holds the promise of a Low Probability of Detection (LPD) system.

DESIGN OF BROADBAND WIRE ANTENNAS FOR FREQUENCY HOPPING APPLICATIONS M.S. Thesis
Keem B. Thiem Mar. 1993 143 p
(AD-A267405) Avail: CASI HC A07/MF A02

For a variety of mechanical and electrical reasons, the U.S. Army prefers to use a wire antenna for its mobile applications in the HF and VHF bands. However, due to the rapid fluctuation of impedance with frequency, a simple wire antenna is not suitable. This research will look into the aspects of electronic switching of the antenna length and electronic switching of the accompanying tuning network for frequency hopping applications. Two separate schemes will be studied. The first one involves a chosen wire antenna loaded with PIN diodes. The diodes will be selectively switched ON or OFF at different frequencies to control the input impedance of the antenna. In the second scheme, a monopole antenna of fixed length will be considered and data on its input impedance over many sub-bands within 30 to 90 MHz will be generated. Tuning networks composed of resistors, inductors, and capacitors will be designed over each sub-band. The various networks will then be connected via PIN diodes and selectively switched to provide matching over a much wider band.

AN APPROXIMATION FOR COMPUTING REDUCTION IN BANDWIDTH REQUIREMENTS USING INTELLIGENT MULTIPLEXERS M.S. Thesis
Lesley J. Henson Mar. 1993 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267434) Avail: CASI HC A05

This paper stochastically models a single-node telecommunications system both with and without the use of intelligent multiplexing. Intelligent multiplexers take advantage of the idle periods or silences that occur during the course of speech transmissions to merge (or multiplex) packetized talkspurts from more than one source onto a single channel. This allows for a more efficient use of available bandwidth, thereby reducing the amount of bandwidth required to carry a particular traffic load. Digitizing speech into packets of equal size also allows for compression, further reducing bandwidth needs. By comparing the models for systems both with and without multiplexing, we are able to determine the reduction in bandwidth which may be expected for a particular grade of service (measured by blocking probabilities). A bivariate continuous time Markov chain model for a multiplexer is presented. An approximation is introduced to calculate limiting blocking probabilities much more quickly and for larger systems than is possible by solving a set of linear equations for the bivariate model. The accuracy of the approximation is explored through comparison with the bivariate model; the approximation provides a somewhat conservative estimate of blocking, but is close enough to be used as a tool for the range of relevant values. The approximation is then used to compare blocking probabilities for three different levels of speech activity. Results are shown in tabular form.

RADOME DEPOLARIZATION EFFECTS ON MONOPULSE RECEIVER TRACKING PERFORMANCE Ph.D. Thesis
Michael A. Temple Jun. 1993 199 p
(AD-A267446; AFIT/DS/ENG/93-03) Avail: CASI HC A09/MF A03

Boresight Error (BSE), defined as the angular deviation between the true position and the apparent position of a target as indicated by radar, is an important figure of merit for a tracking radar. A significant contributor to system BSE is the protective radome. This research effort employed a GO technique to investigate the effects of a radome on BSE, expanding previous ray-trace receiving techniques to include the following: (1) a uniquely defined/developed mathematical description for each surface within arbitrary multi-layer tapered radomes; (2) an 'ideal' taper function concept for obtaining optimum BSE prediction performance; (3) a generalized technique for calculating specular reflection points within the radome; and (4) the total retractive effects along ray propagation paths. Computer model results were compared with limiting case data (BSE = 0 deg), published experimental data, and production system acceptance test data. For all limiting cases, 'system' modeling error was less than .06 mRad. 'Excellent' (BSE within +/- 1 mRad) results were obtained using a hemispheric radome with a displaced aperture gimbal point; predicted BSE values were within +/-1 mRad of published experimental data. Likewise, BSE predictions for the production system were within +/-0.5 mRad of measured data over a 30 deg scan range. Ray refractive effects on BSE prediction were characterized using the validated model.

EVALUATION OF SITE EFFECTS ON A HIGH FREQUENCY DIRECTION FINDING SINGLE SITE LOCATION SYSTEM M.S. Thesis
Gerasimos D. Milatos Mar. 1993 128 p
(AD-A267465) Avail: CASI HC A07/MF A02

An important resource for Signal Intelligence activity in High Frequency Direction Finding (HFDF) is the use of Single Site Location (SSL) systems. Present research and development is aimed at developing tactical, mobile, easy to deploy SSL systems for locating hostile HF transmitters. These systems can detect, determine azimuth and elevation angles of incoming signals, and using ionospheric height information can calculate emitter location. The success or failure of SSL systems is dependent on many different factors, some of which are associated with site effects. System operation over different ground parameters can affect the accuracy of locating emitters. In this thesis, the performance of an 'X' shaped interferometer HF SSL system is examined using the Numerical Electromagnetics Code (NEC). Performance in the presence of two different types of lossy ground conditions are investigated.

THE INFLUENCE OF THE LEVEL FORMANTS ON THE PERCEPTION OF SYNTHETIC VOWEL SOUNDS [WPLYW POZIOMU FORMANTOW NA PERCEPCJE SYNTETYCZNYCH DZWIEKOW SAMOZGLOSKOWYCH]
Henryk Kubzdela and Mariuz Owsianny 1991 39 p In POLISH
(IFTR-41/1991) Avail: CASI HC A03/MF A01

A computer model of a generator of periodic complex sounds simulating consonants was developed. The system makes possible independent regulation of the level of each of the formants and instant generation of the sound. A trapezoid approximates the curve of the spectrum within the range of the formant. In using this model, each person in a group of six listeners experimentally selected synthesis parameters for six sounds that to him seemed optimal approximations of Polish consonants. From these, another six sounds were selected that were identified by a majority of the six persons and several additional listeners as being best qualified to serve as prototypes of Polish consonants. These prototypes were then used to randomly create sounds with various combinations at the level of the second and third formant and these were presented to seven listeners for identification. The results of the identifications are presented in table form in three variants and are described from the point of view of the requirements of automatic recognition of consonants in continuous speech. MEASUREMENTS OF THE RADAR CROSS SECTION AND INVERSE SYNTHETIC APERTURE RADAR (ISAR) IMAGES OF A PIPER NAVAJO AT 9.5 GHz AND 49 GHz Final Report, FY1991 - FY1993
R. Dinger, G. Kinzel, W. Lam, and S. Jones Jan. 1993 48 p
(AD-A267570; NRAD-TR-1569) Avail: CASI HC A03/MF A01

Studies were conducted of the enhanced radar cross section (RCS) and improved inverse synthetic aperture radar (ISAR) image quality that may result at millimeter-wave (mmw) frequencies. To study the potential for mmw radar in these areas, a program was initiated in FY-90 to design and fabricate a 49.0- to 49.5-GHz stepped-frequency radar. After conducting simultaneous measurements of the RCS of an airborne Piper Navajo twin-engine aircraft at 9.0 and 49.0 GHz, the RCS at 49.0 GHz was always found to be higher than at 9.0 GHz by an amount that depended on the target aspect angle. The largest increase was 19 dB and was measured at nose-on incidence; at other angles of incidence, the increase ranged from 3 to 10 dB. The increase averaged over a 360-degree aspect-angle change was 7.2 dB. The 49.0-GHz radar has demonstrated a capability to gather well-calibrated millimeter-wave RCS data of flying targets. In addition, the successful ISAR images obtainable with short aperture time suggest that 49.0-GHz radar may have a role to play in noncooperative target identification (NCTI). DTIC

This research in computational electromagnetics developed a new method for predicting the near-field mutual coupling effects in phased array antennas, using the finite element method (FEM) in combination with integral equations. Accurate feed modeling is accomplished by enforcing continuity between the FEM solution and an arbitrary number of wave guide models across a ground plane aperture. A periodic integral equation is imposed above the antenna's physical structure in order to enforce the radiation condition and to confine the analysis to an array unit cell. The electric field is expanded in terms of vector finite elements, and Galerkin's method is used to write the problem as a matrix equation. A general-purpose computer code was developed and validated by comparing its results to published data for several array types. Its versatility was demonstrated with predictions of the scanning properties of arrays of printed dipoles and printed flared notches. DTIC

MILITARY SATELLITE COMMUNICATIONS: OPPORTUNITY TO SAVE BILLIONS OF DOLLARS. REPORT TO THE CHAIRMAN, LEGISLATION, AND NATIONAL SECURITY SUBCOMMITTEE, COMMITTEE ON GOVERNMENT OPERATIONS, HOUSE OF REPRESENTATIVES
Jul. 1993 18 p
(AD-A267627; GAO/NSIAD-93-216) Avail: CASI HC A03/MF A01

During the past several years, the Congress has been critical of DOD's management of satellite communications-a primary concern being high costs. In August 1989, the House Appropriations Committee expressed concern that DOD's satellite communications architecture was in a state of disarray. It directed DOD to provide a comprehensive plan, defining all satellite communications requirements and potential solutions to meet the requirements within realistic resource levels. In October 1990, during deliberations on the fiscal year 1991 defense appropriations bill, the conference committee expressed dissatisfaction with the plan that DOD had provided in March 1990. The committee was concerned about the lack of a comprehensive architecture and directed DOD to submit a clear and affordable plan with the fiscal year 1992 defense budget request. DTIC

TRUE TIME DELAY OPTICALLY CONTROLLED DUAL BAND TRANSMITTER Report, Feb. - Dec. 1992
Serey Thai May 1993 43 p
(AD-A267663; RL-TR-93-84) Avail: CASI HC A03/MF A01

The main principal of this microwave multiband phased array antenna is the use of optically controlled photonic delay line for beam forming and steering. This system is suitable for spaceborne and airborne phased array applications. It also has a potential to perform frequency hopping of transmitting signals since it is a dual band transmitter (L and X-band) and the dual band system is controlled by one set of frequency independent delay lines. The L-band (1 to 2.6 GHz) array and the X-band (8 to 12 HGz) array, each has the same physical length. Each is split into four subarrays and use a common time delay generator for each subarray on both bands. True time delay with wideband radiating elements permits large transmit and receive frequency excursions without beam wander (beam squint) as the frequency is changed, and also permits the use of wideband waveforms. The advantage also extends to both communications and surveillance applications where the beam wanders off target could occur without the use of the optically controlled true time delay beam forming and steering. BACKSCAT LIDAR SIMULATION VERSION 3.0: TECHNICAL DOCUMENTATION AND USERS GUIDE
John R. Hummel, David R. Longtin, Nanette L. DePiero, and Robert J. Grasso 3 Dec. 1992 128 p
(Contract F19628-91-C-0093)
(AD-A267296; LTR92-017; PL-TR-92-2328; AD-E201501) Avail: CASI HC A07/MF A02

The Geophysics Directorate of Phillips Laboratory is developing a number of lidar systems for use in probing the atmosphere. These systems include backscatter lidars to study atmospheric aerosols, Doppler lidar systems to measure wind fields, and Raman lidars to study the distributions of different molecular species. To aid in the design and use of such lidar systems, SPARTA has developed a lidar simulation program, BACKSCAT. Originally developed to include only the backscattered return from aerosols, the simulation package has evolved to include Raman scattering processes. BACKSCAT Version 3.0 includes two significant improvements. The first is the inclusion of user-defined aerosol layers and the second is the consideration of Raman scattering processes. In BACKSCAT Version 3.0, a user-defined aerosol layer is defined by a number density profile, a size distribution shape, and an index of refraction. Aerosol attenuation properties are computed using an efficient Mie scattering program that is coupled to the BACKSCAT simulation system. Users can select from a library of aerosol indices of refraction for common aerosols or they can input specific values. DTIC

The Kapitza facility is a pulse forming network consisting of an energy

source, semiconductor opening switch, pulse transformer and a load. To characterize the Kapitza facility, there is a need for a measurement system where the sensors are completely separated electrically from the Data Acquisition System. A measurement system based upon fiber-optic data transmission was finally chosen. This fiber-optic system, with a bandwidth of 1 MHz, uses FM transmission techniques; the data input is used to frequency modulate the optical carrier that is coupled to the fiber, and subsequently demodulated at the receiver to recover the analog signal. In this report the operation of the optical measurement system, the components that have been used and the calibration of the transmitter/receiver units are some of the subjects that are discussed. In the appendix, schematics, print layouts, lists with the used components, wave forms of the input output signals and specifications are given. DTIC

NOTES ON THE USE OF DEMPSTER-SHAFER AND FUZZY REASONING TO FUSE IDENTITY ATTRIBUTE DATA
D. J. Kewley Aug. 1992 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267426; SRL-0094-TM; DODA-AR-007-012) Avail: CASI HC A03

Dempster-Shafer evidential reasoning (D-S) has been applied to fusion of identity attribute data by Filippidis and Schapel. Their example involved deciding, from a given list, which radar emitter was producing the frequency and pulse rate measured by an ESM receiver. The D-S method was used to reach conclusions under uncertainty. Here an alternative approach using fuzzy reasoning is compared to their results. It is seen that the same conclusions are reached with a considerable reduction in computation. The ability to consider new data after a conclusion is reached is seen to be an additional reason for favoring the use of fuzzy reasoning for data fusion of this type. A discussion on the relationship between the approaches is provided. DTIC

MICRO PULSE LASER RADAR Patent Application
James Spinhirne, inventor (to NASA) 13 Aug. 1992 35 p
(NASA-Case-GSC-13493-1; NAS 1.71:GSC-13493-1;
US-Patent-Appl-SN-929216) Avail: CASI HC A03/MF A01

An eye safe, compact, solid state lidar for profiling atmospheric cloud and aerosol scattering is disclosed. The transmitter of the micro pulse lidar is a diode pumped micro-J pulse energy, high repetition rate Nd:YLF laser. Eye safety is obtained through beam expansion. The receiver employs a photon counting solid state Geiger mode avalanche photodiode detector. Data acquisition is by a single card multichannel scaler. Daytime background induced quantum noise is controlled by a narrow receiver field-of-view and a narrow bandwidth temperature controlled interference filter. Dynamic range of the signal is limited to optical geometric signal compression. Signal simulations and initial atmospheric measurements indicate that micropulse lider systems are capable of detecting and profiling all significant cloud and aerosol scattering through the troposphere and into the stratosphere. The intended applications are scientific studies and environmental monitoring which require full time, unattended measurements of the cloud and aerosol height structure. NASA

REMOTE SENSING OF PRECIPITATION AND ELECTRIFICATION WITH A DUAL-POLARIZATION, COHERENT, WIDEBAND RADAR SYSTEM Final Report, 15 Jul. 1989 - 14 Jul. 1993
Paul Krehbiel and Grant Gray 10 Jul. 1993 31 p
(Grant AF-AFOSR-0450-89)
(AD-A267479; AFOSR-93-0564TR) Avail: CASI HC A03/MF A01

Electrical alignment of precipitation particles was detected in an electrified storm using the co- and cross-polar channels of the radar. The radar receiver chain was upgraded and modern signal processing and display equipment added. The system was taken to Kennedy Space Center for final checkout and data-gathering independently and in conjunction with the CaPE program. Using the cross-polar correlation magnitude and phase displays as a guide, it was possible to accurately predict the outset of electrification and attendant lightning discharges, and to determine when a storm would no longer produce lightning. Several publications documenting the effect are included. A patent on the cross-polar correlation technique is being sought. DTIC

AN ELECTROMAGNETIC INTERFERENCE STUDY OF POTENTIAL TRANSMITTER SITES FOR THE HF ACTIVE AURORAL RESEARCH PROGRAM (HAARP) Interim Report
Joseph A. Goldstein, Edward J. Kennedy, Adrian S. Eley, and Michael A. Rupar 19 Jul. 1993 41 p
(AD-A267743; NRL/MR/5554-93-7375) Avail: CASI HC A03/MF A01

This report presents the results of Electromagnetic Interference (EMI) measurements conducted by the Naval Research Laboratory in June of 1991. This study examined a number of potential sites for the location of the proposed High Frequency Active Auroral Research Program (HAARP) transmitter facility. The proposed HAARP facility will consist of a large planar array of antennas excited by phased high power transmitters operating in the lower portion of the HF band (2.8 to 8 MHz). Several candidate locations were identified for study in the vicinity of Fairbanks, Alaska. The magnitude of EMI in the population centers and on other commercial and public facilities in the vicinity of Fairbanks from the high power transmitter is a major factor in the site selection process for HAARP. The EMI investigations were conducted in two phases. For Phase I of the study, EMI measurements were conducted at two receiver locations using an airborne transmitter at thirteen potential HAARP sites. The results from the Phase 1 measurements were examined and the two most promising candidate transmitter locations were selected for more comprehensive measurements during Phase 2. For Phase 2, comprehensive EMI measurements were made for each of the two candidate transmitter sites. Field strengths were measured at a variety of receiver locations that are representative of the impact area for the EMI from HAARP. The results for both the Phase 1 and Phase 2 measurements are presented in this report. DTIC

Pulse to pulse radar echo fluctuations were used to distinguish rain from anomalous propagation clutter. For one deg sectors at a fixed range 14 echo samples from successive pulses are tested for clutter. This test has a clutter detection rate of only 45 percent, but in each 1 deg/km polar radar pixel 8 range bins can be tested. The 8 tests are shown to be

nearly independent and their combined result allows 85 percent of the clutter pixels to be detected. The pattern of suspect pixels in the completed radar picture is analyzed on a scale of about 10 km. The total result is an average removal efficiency of about 98 percent. Only echoes of very light precipitation are erroneously suppressed by this processing: at most 5 percent of light rain pixels or 15 percent of light snow pixels are removed. For online application this method requires a fast preprocessor operating in combination with the radar's digital signal integrator. ESA

HIGH ORDER NONLINEAR ESTIMATION WITH SIGNAL PROCESSING APPLICATIONS
T. W. Hilands Aug. 1993 252 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268407; PSU/ARL/TR-93-08) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two high order vector filters (HOF's) are developed for estimation in non-Gaussian noise. These filters are constructed using nonlinear functions of the innovations process. They are completely general in that the initial state covariance, the measurement noise covariance, and the process noise covariance can all have non-Gaussian distributions. The first filter is designed for systems with asymmetric probability densities. The second is designed for systems with symmetric probability densities. Experimental evaluation for estimation in non-Gaussian noise, formed from Gaussian sum distributions, shows that these filters perform much better than the standard Kalman filter, and close to the optimal Bayesian estimator. The problem of high resolution parameter estimation of superimposed sinusoids is addressed using nonlinear filtering techniques. Six separate nonlinear filters are evaluated for the estimation of the parameters of sinusoids in white and colored Gaussian noise. Experimental evaluation demonstrates that the nonlinear filters perform close to the Cramer-Rao bound for reasonable values of the initial estimation error. The recursive technique developed here is well suited for time-varying systems and for measurements with short data lengths. DTIC

APPLICATION OF THE FINITE-DIFFERENCE TIME-DOMAIN METHOD TO SCATTERING AND RADIATION PROBLEMS INVOLVING WIRES AND PLATES Final Report
B. Beker Dec. 1992 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268396; NCCOSD/RDT/E-TD-2516) Avail: CASI HC A03

Numerical modeling of electromagnetic (EM) interaction is normally performed by using either differential or integral equation methods. Both techniques can be implemented to solve problems in frequency or time domain. The method of moments (MOM) approach to solving integral equations has matured to the point where it can be used to solve complex problems. In the past, MOM has only been applied to scattering and radiation problems involving perfectly conducting or isotropic penetrable, lossy or lossless objects. However, many materials, (e.g., composites that are used on the Navy's surface ships in practical applications) exhibit anisotropic properties. To account for these new effects, several integral equation formulations for scattering and radiation by anisotropic objects have been developed recently. The differential equation approach to EM interaction studies has seen the emergence of the finite-difference time-domain (FD-TD) method as the method of choice in many of today's scattering and radiation applications. This approach has been applied to study transient as well as steady-state scattering from many complex structures, radiation from wire antennas, and coupling into wires through narrow apertures in conducting cavities. It is important to determine whether or not, and how effectively, the FD-TD can be used to solve EM interaction problems of interest to the Navy, such as investigating potential EM interference in shipboard communication systems. Consequently, this report partly addresses this issue by dealing exclusively with FD-TD modeling of time-domain EM scattering and radiation. DTIC

Modern C3I systems are best described as semi-automated data management and decision systems over which human operators exercise supervisory control. The effectiveness of such systems is heavily dependent on the design for human-computer interaction (HCI), an important aspect of which is the visual display interface. Current Department of Defense policy mandates consideration of such human factors issues at an early stage in the design process. Comprehensive guidelines are available for display design applications after the general system parameters have been specified. Some recommendations are general, others are specific. This report offers a set of design principles at an intermediate (conceptual) level of abstraction as a complement to existing guidelines. The purpose is to synthesize current knowledge of human cognition into a form that will be applicable to the earliest stages of display design ('cognitive' functions being the most salient and critical of those remaining for the operator in advanced C3I systems). The principles are derived from a review of the literatures on human cognition, HCI, and display design, some original research, and liberal interpretation by the authors. They are organized according to operations performed on specific categories of information in possible C3I task configurations. DTIC

The National Aeronautics and Space Administration (NASA) and the National Science Foundation (NSF) commissioned a panel of U.S. experts to study the international status of satellite communications systems and technology. The study covers emerging systems concepts, applications, services, and the attendant technologies. The panel members travelled to Europe, Japan, and Russia to gather information first-hand; they visited 17 sites in Europe, 20 sites in Japan, and four in Russia. These included major manufacturers, government organizations, service providers, and associated R&D facilities. The panel's report was reviewed by the sites visited, by the panel, and by representatives of U.S. industry. The report details the information collected and compares it to U.S. activities.

VLSI FOR HIGH-SPEED DIGITAL SIGNAL PROCESSING Quarterly Report, 1 Apr. - 30 Jun. 1993
Alan N. Willson, Jr. 30 Jun. 1993 5 p
(Contract N00014-91-J-1852)
(AD-A267709) Avail: CASI HC A01/MF A01

During the past quarter, we have begun testing our single-processor IC's which we received from MOSIS. The chip provides for 11-bit input and output data with 16-bit internal data and 12-bit coefficients (stored in on-chip memory). The chip also has an 8-bit microprocessor bus interface for loading programs and coefficients. The IC contains 25,000 transistors

and occupies an area of 14.8 sq. mm (3.7 mm by 4.0 mm including pads) in 1.2-micron CMOS technology. A block diagram of the chip is shown. Initial testing shows that the chip is fully functional. We are in the process of testing the performance and power dissipation of the chip and characterizing the input and output timing. From simulations we expect the chip to operate at 50 MHz. DTIC

CIRCUITS AND CONTROL PROCESSES FOR COMBINING DIRECT CONVERTERS AND INVERTER MOTORS Ph.D. Thesis [SCHALTUNGEN UND STEUERVERFAHREN FUER DIE KOMBINATION VON DIREKTUMRICHTER UND STROMRICHTERMOTOR]

Michael Mehne 1992 131 p In GERMAN
(ETN-93-94399) Avail: CASI HC A07/MF A02

A method for inferior and superior engine speed range definition of a synchronous machine is proposed and conditions for operation interchange of direct converters and inverter motors are demonstrated. Several configurations of direct/inverse converters used as inverter motors with multiple intermediate devices were compared by simulation. It is established that the machine frequency must be chosen in the interval 5 to 12.5 Hz. The spectrum of network currents in direct operation was calculated from the simulated time curves and is found to be similar to this one of a comparable direct inverter. A higher network connection voltage is shown to be necessary for high numbers of revolution and the direct/inverse converter is found to have a lower power factor in direct operating for equal number of revolutions. It is concluded that direct/inverse converters are a powerful alternative to the well known starting processes of invertor motors and they make superfluous a system separation between direct converter and inverter motor for high power drive in any engine speed range. INTEGRATED FUNDAMENTAL RESEARCH ON CURRENT COLLECTION Final Report, Feb. 1989 - Sep. 1992

Doris Kuhlmann-Wilsdorf and Leo Tran Jun. 1993 53 p
(Contract DAAA21-89-C-0027)
(AD-A266987; UVA/525234/MSE93/101; ARFSD-CR-93004) Avail: CASI HC A04/MF A01

The aim of our research was to add to the basic understanding in the area of current collection with particular emphasis on topics likely to benefit practical objectives. Under sponsorship of this contract, 23 papers were published in the international literature. Additionally, 13 invited lectures and 11 contributed lectures on various aspects of this research were delivered at universities, research laboratories, and international conferences by the principal investigator and co-workers. The development of a novel metal fiber material for sliding electrical contacts was continued with much success. This is expected to become very useful for making metal fiber brushed for homopolar motors/generators, as well as for EML armatures. Included in this report are title pages (and abstracts) for the 23 published papers. Author (revised)

(NASA-CR-194587; NAS 1.26:194587) Avail: CASI HC A05/MF A01

This annual report outlines the activities of the past year at the NASA SERC on VLSI Design. Highlights for this year include the following: a significant breakthrough was achieved in utilizing commercial IC foundries for producing flight electronics; the first two flight qualified chips were designed, fabricated, and tested and are now being delivered into NASA flight systems; and a new technology transfer mechanism has been established to transfer VLSI advances into NASA and commercial systems. A STUDY OF HIGH FIELD TRANSPORT IN WIDE BAND GAP ELECTRONIC MATERIALS USING A PICOSECOND TRANSIENT CHARGE TECHNIQUE Semiannual Report, 30 Nov. - 2 Jul. 1993

Craig J. Scott 2 Jul. 1993 9 p
(Contract N00014-93-1-0128)
(AD-A267098) Avail: CASI HC A02/MF A01

We propose a study of electron and hole traps and carrier drift velocity for high electric field strengths using the transient charge technique (TCT) with a picosecond electron beam probe. The uniqueness in the proposed approach lies in the use of a photocathode SEM to generate picosecond electron pulses with high lateral resolution to generate electron hole pairs. Ultrafast electron beam pulses allow narrow drift regions to be characterized and allow high field measurements to be performed without thermal heating. DTIC

FAULT HANDLING SCHEMES IN ELECTRONIC SYSTEMS WITH SPECIFIC APPLICATION TO RADIATION TOLERANCE AND VLSI DESIGN Final Report, 3 Jan. 1989 - Oct. 1993

John Okyere Attia Oct. 1993 106 p
(Grant NAG9-337)
(NASA-CR-194559; NAS 1.26:194559) Avail: CASI HC A06/MF A02

Naturally occurring space radiation particles can produce transient and permanent changes in the electrical properties of electronic devices and systems. In this work, the transient radiation effects on DRAM and CMOS SRAM were considered. In addition, the effect of total ionizing dose radiation of the switching times of CMOS logic gates were investigated. Effects of transient radiation on the column and cell of MOS dynamic memory cell was simulated using SPICE. It was found that the critical charge of the bitline was higher than that of the cell. In addition, the critical charge of the combined cell-bitline was found to be dependent on the gate voltage of the access transistor. In addition, the effect of total ionizing dose radiation on the switching times of CMOS logic gate was obtained. The results of this work indicate that, the rise time of CMOS logic gates increases, while the fall time decreases with an increase in total ionizing dose radiation. Also, by increasing the size of the P-channel transistor with respect to that of the N-channel transistor, the propagation delay of CMOS logic gate can be made to decrease with, or be independent of an increase in total ionizing dose radiation. Furthermore, a method was developed for replacing polysilicon feedback resistance of SRAMs with a switched capacitor network. A switched capacitor SRAM was implemented using MOS Technology. The critical change of the switched capacitor SRAM has a very large critical charge. The results of this work indicate that switched capacitor SRAM is a viable alternative to SRAM with polysilicon feedback resistance. Author

RELIABILITY CHARACTERIZATION OF DIGITAL MICROCIRCUITS: INVESTIGATION OF AN IN-PROCESS OXIDE RELIABILITY SCREENING METHOD Final Report, Jan. 1991 - Nov. 1992

Chung P. Wu Apr. 1993 118 p
(Contract F30602-90-C-0063)
(AD-A267053; RL-TR-93-41) Avail: CASI HC A06/MF A02

This report covers the work performed, using a sacrificial-metal-pattern technique, to demonstrate a 100% in-process screen for oxide defects in high-density CMOS microcircuits, and to evaluate the effectiveness and side effects of the added processing steps on yield and reliability. Using large-area polysilicon capacitors and 101-stage metal-1 delay-lines in GEM WAT keys as test vehicles, experiments with split lot reliability screening and life test, first with 240 A and again with 150 A gate oxide, have demonstrated practically complete elimination of the defective populations

for test capacitors and about 50% reduction in circuit functionality failures for delay-line circuits. This is accomplished with little or no penalty in metal-polysilicon contact resistance, or in delay-line circuit yield. The technique is found to be promising and should be further investigated with more complex circuits with double-level metals. DTIC

A METHOD OF DETECTING AND LOCATING ELECTRICAL CURRENT IMBALANCES Patent Application
Richard L. Patterson, inventor (to NASA) 21 Jan. 1993 16 p
(NASA-Case-LEW-15407-1; NAS 1.71:LEW-15407-1;
US-Patent-Appl-SN-006413) Avail: CASI HC A03/MF A01

A method of detecting and locating current imbalances such as ground faults in multiwire systems using the Faraday effect is described. As an example, for 2-wire or 3-wire (1 ground wire) electrical systems, light is transmitted along an optical path which is exposed to magnetic fields produced by currents flowing in the hot and neutral wires. The rotations produced by these two magnetic fields cancel each other, therefore light on the optical path does not read the effect of either. However, when a ground fault occurs, the optical path is exposed to a net Faraday effect rotation due to the current imbalance thereby exposing the ground fault. NASA

MOLTEN SALT ELECTRODEPOSITION OF HIGH TEMPERATURE SUPERCONDUCTORS Final Report, 7 Sep. 1990 - 30 Nov. 1992
D. M. Tench, M. W. Kendig, and S. Jeanjaquet Jun. 1993 52 p
(Contract N00014-90-C-0225)
(AD-A266620; SC71033.FR) Avail: CASI HC A04/MF A01

The overall objective of this project was to develop a process for direct electrodeposition of Y-Ba-Cu superconducting oxides from a molten salt at relatively low temperatures (300-550 deg C). An important finding was that cathodic deposition of metallic oxides, rather than free metals, generally occurs from nitrate melts, apparently via reduction of metal nitrato complexes. Oxide deposition was confirmed for Cu as CuO, Y as Y2O3, and Co as Co304, and apparently also occurs for Ba. Deposition of mixed Ba-Y-Cu oxides was demonstrated on both Cu and Pt substrates. Data were compiled that provide a good basis for designing schemes for deposition of various mixed oxides from nitrate melts. A sequential anodic injection method was conceived for depositing ultrathin mixed oxide layers, which can be viewed as an analog of molecular beam epitaxy. Results obtained with this approach were encouraging but were inconclusive because of contamination with Gd from the Y injection anode. Based on the results of this program and literature studies, cathodic metal oxide deposition from nitrate melts is a general phenomenon that could ultimately prove to be a practical means of preparing a variety of single and mixed anhydrous metal oxide films. It is recommended that future work focus initially on deposition of perovskite materials, which are of considerable practical interest and involve only two metallic components so that the required deposition schemes are inherently simpler. DTIC

CRYOGENIC MEASUREMENTS OF AEROJET GaAs n-JFETs
John H. Goebel and Theodore T. Weber Sep. 1993 62 p
(RTOP 590-31-11)
(NASA-TM-103972; A-92177; NAS 1.15:103972) Avail: CASI HC A04/MF A01

The spectral noise characteristics of Aerojet gallium arsenide (GaAs) junction field effect transistors (JFET's) have been investigated down to liquid-helium temperatures. Noise characterization was performed with the field effect transistor (FET) in the floating-gate mode, in the grounded-gate mode to determine the lowest noise readings possible, and with an extrinsic silicon photodetector at various detector bias voltages to determine optimum operating conditions. The measurements indicate that the Aerojet GaAs JFET is a quiet and stable device at liquid helium temperatures. Hence, it can be considered a readout line driver or infrared detector preamplifier as well as a host of other cryogenic applications. Its noise performance is superior to silicon (Si) metal oxide semiconductor field effect transistor (MOSFET's) operating at liquid helium temperatures, and is equal to the best Si n channel junction field effect transistor (n-JFET's) operating at 300 K. STRESS SENSITIVITY OF DIELECTRIC RESONATORS Final Report, 19 Mar. 1990 - 18 Mar. 1993
Peter C. Lee 14 Jun. 1993 5 p
(Contract DAAL03-90-G-0079)
(AD-A266767; ARO-26909.6-MA) Avail: CASI HC A01/MF A01

The objective of research is to investigate the sensitivity of the frequency-shifts of the guided EM waves in dielectric resonators when they are subjected to external forces, shocks, or vibrations. Forces applied to a resonator produce stresses which, through the nonlinear piezooptical effect, changes the permittivity constant into an inhomogeneous, second-order permittivity tensor, depending upon the spatial distribution of

stresses. This changing in material property, in turn, affects the velocities and couplings of EM waves inside the resonator and hence causes the shifts of resonances. Closed form solutions of the 3-D Maxwell's equations for finite resonators are very few and they are known only for solid sphere and torus of homogeneous isotropic dielectrics. In order to study the problems of stress effect on the vibrations in dielectric plate resonators, circular or rectangular, in a systematic way, the research is conducted according to the following sequence. A system of 2-D equations for guided waves is deduced from the 3-D Maxwell's equations. Closed form solutions are obtained from these 2-D equations for circular disks embedded in free space. Then the stress sensitivity of guided waves in circular isotropic disks and in infinite anisotropic plates are studied. DTIC

FORBACK DC-TO-DC CONVERTER Patent Application

Alan T. Lukemire, inventor (to NASA) 24 Mar. 1993 33 p

(NASA-Case-GSC-13404-1; NAS 1.71:GSC-13404-1;

US-Patent-Appl-SN-038746) Avail: CASI HC A03/MF A01

A pulse-width modulated DC-to-DC power converter including a first inductor, i.e. a transformer or an equivalent fixed inductor equal to the inductance of the secondary winding of the transformer, coupled across a source of DC input voltage via a transistor switch which is rendered alternately conductive (ON) and nonconductive (OFF) in accordance with a signal from a feedback control circuit is described. A first capacitor capacitively couples one side of the first inductor to a second inductor which is connected to a second capacitor which is coupled to the other side of the first inductor. A circuit load shunts the second capacitor. A semiconductor diode is additionally coupled from a common circuit connection between the first capacitor and the second inductor to the other side of the first inductor. A current sense transformer generating a current feedback signal for the switch control circuit is directly coupled in series with the other side of the first inductor so that the first capacitor, the second inductor and the current sense transformer are connected in series through the first inductor. The inductance values of the first and second inductors, moreover, are made identical. Such a converter topology results in a simultaneous voltsecond balance in the first inductance and ampere-second balance in the current sense transformer. NASA

CELLULOSE TRIACETATE, THIN FILM DIELECTRIC CAPACITOR Patent Application

Shiao-Ping S. Yen, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and T. Richard Jow, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 28 May 1993 13 p

(Contract NAS7-918)

(NASA-Case-NPO-18935-1-CU; NAS 1.71:NPO-18935-1-CU;

US-Patent-Appl-SN-071416) Avail: CASI HC A03/MF A01

Very thin films of cellulose triacetate are cast from a solution containing a small amount of high boiling temperature, non-solvent which evaporates last and lifts the film from the casting surface. Stretched, oriented, crystallized films have high electrical breakdown properties. Metallized films less than about 2 microns in thickness form self-healing electrodes for high energy density, pulsed power capacitors. Thicker films can be utilized as a dielectric for a capacitor. FULLERENE SUPERCONDUCTORS Final Report, 15 May 1992 - 14 Mar. 1993

Richard B. Kaner 17 Jun. 1993 2 p

(Contract DAAL03-92-G-0188)

(AD-A266749; ARO-29708.7-CH) Avail: CASI HC A01/MF A01

The electrical, magnetic and optical properties of the fullerene superconductors K3C60 and Rb3C60 have been investigated. The room temperature microwave resistivity at 60 GHz of pressed powder samples of K3C60 is approximately 5m (ohms) cm. The resistivity drops by almost one order of magnitude on cooling to 20K, indicative of metallic behavior, before the samples superconduct at T (sub) c = 19.3K. Optical reflectivity spectra are consistent with metallic materials. An extrapolation of the frequency dependence of conductivity leads to d.c. conductivities of 1.3 x 10 (exp 3) (ohm)-I and 1.2 x 10 (exp 3) (ohm)-I for K3C60 and Rb3C60, respectively. The gap values A of 24 /cm for K3C60 and 30 /cm for Rb3C60 are consistent with weak-coupling and a BCS singlet ground state. Upper critical fields of 26-30 Tesla for K3C60 and 38-55 Tesla for Rb3C60 have been measured. The lower values are from static magnetic experiments, while the upper values used pulsed magnets. DTIC

CIRCLE DIAGRAM APPROACH FOR SELF EXCITED INDUCTION GENERATORS

E. Muljadi, P. W. Carlin, and R. M. Osgood May 1993 6 p

(Contract DE-AC02-83CH-10093)

(DE93-010031; NREL/TP-441-5611) Avail: CASI HC A02/MF A01

When an induction generator is connected to a utility line supply, the voltage and frequency at the terminal output are the same as the voltage and frequency of the utility line supply to which the generator is connected. The reactive power needed by the induction generator is supplied by the utility and the real power is returned to the utility. With a fixed frequency dictated by the utility, the induction machine starts generating above the synchronous speed. The range of speed is also limited by the slip. At a very high slip, the copper losses increases as the current increases. On the other hand, in an isolated operation, the induction generator operates in self-excitation mode. It determines its own voltage and frequency. These two quantities depend on the size of the AC capacitor, the induction machine parameters, the electrical load, and the speed of the generator. The operating speed of the induction generator is extended without generating excessive loss. This paper presents an analytical study by utilizing a circle diagram to illustrate the operation of the induction generator in isolated operation. The steady-state calculations are presented to support the analysis. Possible applications for the system in variable-speed generation are currently under investigation. The output can be directly connected to equipment that is non-sensitive to the frequency (a heater, battery charger, etc.) or can be connected to a converter to get a fixed-frequency AC output. DOE

A DEVICE FOR TESTING CABLES Patent Application

Arthur Ray Hayhurst, inventor (to NASA) 7 Jun. 1993 12 p

(NASA-Case-LAR-14093-1; NAS 1.71:LAR-14093-1;

US-Patent-Appl-SN-073845) Avail: CASI HC A03/MF A01

A device for testing current paths is attachable to a conductor. The device automatically checks the current paths of the conductor for continuity of a center conductor, continuity of a shield, and a short circuit between the shield and the center conductor. The device includes a pair of connectors and a circuit to provide for testing of the conductive paths of a cable to be tested with the circuit paths of the circuit. The circuit paths in the circuit include indicators to simultaneously indicate the results of the testing. NASA

IN SITU RAMAN SPECTROSCOPY OF LITHIUM ELECTRODE SURFACE IN AMBIENT TEMPERATURE LITHIUM SECONDARY BATTERY

Hiroyasu Tachikawa Sep. 1992 18 p

(Contract DE-AC03-76SF-00098)

(DE93-015238; LBL-33046) Avail: CASI HC A03/MF A01

Raman spectroscopy was used to characterize surface layers on lithium electrodes in different solvents such as propylene carbonate (PC), dimethyl carbonate (DMC), diethyl carbonate (DEC), and polyethylene glycol 400 dimethyl ether (PEG400DME). Both DMC and DEC were used singly, and also mixed with either methyl acetate (MA) or methyl formate (MF). The Raman spectra showed that passive films formed on the Li surface in different solvents may have different chemical structures, which changed during the charging and discharging processes. Raman spectroscopy was also applied to characterize zinc electrode surfaces in alkaline solutions. The results suggested that ZnO and Zn(OH)(2) formed on the Zn electrode when a passive potential was applied. A solid film of fullerene C60, which could be used as a cathode in Li rechargeable batteries, was examined in the PEG400DME solution by both electrochemical and Raman spectroscopy. Cyclic voltammograms (CV's) showed five redox peaks which suggested

the formation of C60(-), C60(2-), C60(3-), C60(4-), and C60(5-). Raman spectra obtained from a thin C60 film indicated that the thin fulleride film dissolved in the PEG400DME/LiClO4 solution at negative potentials. DOE

CONTROLS OF MAGLEV SUSPENSION SYSTEMS
Y. Cai, S. Zhu, S. S. Chen, and D. M. Rote 1993 43 p Presented at the Pressure Vessels and Piping Conference, Denver, CO, 25-29 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-015540; ANL/MCT/CP-78162; CONF-930702-41) Avail: CASI HC A03/MF A01

Alternative control designs of maglev vehicle suspension systems were investigated. Active and semi-active control law designs are introduced into primary and secondary suspensions of maglev vehicles. A one-dimensional vehicle with two degrees of freedom, to simulate the German Transrapid Maglev System, is used for suspension control designs. The transient and frequency responses of suspension systems and PSD's of vehicle accelerations are calculated to evaluate different control designs. The results show that active and semi-active control designs indeed improve the response of vehicle and provide an acceptable ride comfort for maglev systems. DOE

UTILITY EMISSIONS ASSOCIATED WITH ELECTRIC AND HYBRID VEHICLE (EHV) CHARGING
Apr. 1993 128 p
(DE93-013734; DOE/CE-0395) Avail: CASI HC A07/MF A02

This project is a joint effort between the U.S. Department of Energy (DOE) and the Electric Power Research Institute (EPRI) to conduct a comprehensive, in-depth assessment of the emission impacts of electric and hybrid vehicles (EHV's). The study determines local and regional emission impacts under a variety of scenarios, covering both conservative and optimistic assumptions about vehicle efficiency, power plant efficiency, and other factors. In all scenarios, EHV use significantly reduces urban emissions of CO, VOC, and TSP. Changes in NO(x) and CO2 emissions are very sensitive to average or marginal power plant emissions and vehicle efficiency assumptions. NOx and CO2 emissions changes vary dramatically by region. Certain combinations of EHV and CV scenarios and regions result in significant reductions, while other combinations result in significant increases. Careful use of these results is advised. In all scenarios, SO2 increases with EHV use although the amount is small--less than 1% of total utility emissions even with the deployment of 12 million EHVS. But because of emission cap provisions of the Clean Air Act Amendments of 1990, national SO2 totals will not be allowed to increase. Thus, utilities will have to apply more stringent measures to combat increased SO2 emissions due to the increased use of electric vehicles. DOE

TRANSLATING WEDGE HEAT SINK Patent
Mark W. Sewell, inventor (to Navy) 8 Jun. 1993 6 p Filed 18 May 1992 Supersedes AD-D015357
(AD-D015814; US-Patent-5,218,517; US-Patent-Appl-SN-884976; US-Patent-Class-361-288) Avail: US Patent and Trademark Office

A device for dissipating heat from cased electronics where optimum heat transfer is required, and where easy removability is desired is described. The device finds utility in sonobuoys, buoys, missiles and mines, as well as cabling electronics such as transoceanic communications equipment. The device contains a translating wedge which is drawn into a forced fit between the heat generating module and a conducting wedge which contacts the electronics case, resulting in a high efficiency conducting thermal path from the electronics to the equipment case. The device is particularly efficate in circular cased electronics. DTIC

LITHIUM D-CELL STUDY Final Report
P. Size and Esther S. Takeuchi 31 Mar. 1993 443 p
(Contract NAS9-18395)
(NASA-CR-192705; NAS 1.26:192705) Avail: CASI HC A19/MF A04

The purpose of this contract is to evaluate parametrically the effects of various factors including the electrolyte type, electrolyte concentration, depolarizer type, and cell configuration on lithium cell electrical performance and safety. This effort shall allow for the selection and optimization of cell design for future NASA applications while maintaining close ties with WGL's continuous improvements in manufacturing processes and lithium cell design. Taguchi experimental design techniques are employed in this task, and allow for a maximum amount of information to be obtained while requiring significantly less cells than if a full factorial design were employed. Acceptance testing for this task is modeled after the NASA Document EP5-83-025, Revision C, for cell weights, OCV's and load voltages. The performance attributes that are studied in this effort are fresh capacity and start-up characteristics evaluated at two rates and two temperatures, shelf-life characteristics including start-up and capacity retention, and iterative microcalorimetry measurements. Abuse testing includes forced over discharge at two rates with and without diode protection, temperature tolerance testing, and shorting tests at three rates with the measurement of heat generated during shorting conditions. HYDRAULIC PUMP WITH INTEGRAL ELECTRIC MOTOR Patent
William E. Schneider, inventor (to Navy) 2 Mar. 1993 8 p Filed 23 Mar. 1992
(AD-D015782; US-Patent-5,190,447; US-Patent-Appl-SN-855827; US-Patent-Class-417-356) Avail: US Patent and Trademark Office

This is a pumping mechanism featuring integration of a fixed displacement radial piston pump within an electric drive motor and cooperative operation of a radially inwardly facing piston-actuating cam with a pair of opposing axially inwardly facing spool-valve actuating cams. The piston-actuating cam is effectively the inner surface of the rotating motor rotor, the pistons extending radially from a fixed central body. Consequent benefits of the integrated configuration are greater quietness, compactness, efficiency and corrosion resistance. The external motor unit provides protection, there is a damping effect, and there are fewer parts which are subject to damage or malfunction. Further reductions in noise and leakage are gained by synchronized operation, in terms of fluid pumping, of the spool-valve actuating cams and the piston-actuating cam. The piston elements can be distributed so as to foster balanced loadings, and the pump flow rate can be controlled by varying the motor's rotational speed, thus advantageously combining the hydraulic pressure balance which is characteristic of a fixed-displacement pump with the variable delivery of a variable-displacement pump. MEASUREMENTS OF THE OPERATION OF THE SINUS-6/BWO SYSTEM Final Report, 1 Sep. - 1 Dec. 1992
Kyle J. Hendricks and Thomas A. Spencer May 1993 22 p
(AD-A266423; AD-E201487; PL-TR-93-1003) Avail: CASI HC A03/MF A01

A series of measurements were completed on the SINUS-6/BWO system presently located at the UNM EECE Dept. These measurements were necessary to establish that the rf and pulse power performances meet the contract specification. Measurements included antenna pattern plots, pulse power diagnostics, and calculations to establish what the microwave system should radiate. The SINUS-6 pulse power device produces V(sub p) approximately 600 kV, I approximately 5 kA, and tau approximately 10 ns at 200 pulses per second. The BWO parameters are P approximately 500 MW, tau approximately 10 ns, and lambda approximately 3 cm (f approximately 10 GHz). The slow wave structure is inserted into a segmented solenoid which produces a magnetic field of B(sub z) approximately 30 kG with axial uniformity over 120 mm at a radius of 20 mm. DTIC

FABRICATION OF ADVANCED DESIGN (GROOVED) CERMET ANODES
C. F. Windisch, Jr. and F. R. Huettig (Ceramic Magnetics, Inc., Fairfield, NJ.) May 1993 54 p
(Contract DE-AC06-76RL-01830)
(DE93-014590; PNL-8622) Avail: CASI HC A04/MF A01

Attempts were made to fabricate full-size anodes with advanced, or grooved, design using isostatic pressing, slip casting injection molding. Of the three approaches, isostatic pressing produced an anode with dimensions nearest to the target specifications, without serious macroscopic flaws. This approach is considered the most promising for making advanced anodes for aluminum smelting. However, significant work still remains to optimize the physical properties and microstructure of the anode, both of which were significantly different from that of previous anodes. Injection molding and slip casting yielded anode materials with serious deficiencies, including cracks and holes. Injection molding gave cermet material with the best intrinsic microstructure, i.e., the microstructure of the material between macroscopic flaws was very similar to that of anodes previously made at PNL. The reason for the similarity may have to do with amount of residual binder in the material prior to sintering. DOE

LARGE SIGNAL CHARACTERIZATION AND MODELING OF HETEROJUNCTION BIPOLAR TRANSISTORS Final Report, 1 Jun. 1990 - 31 May 1993
D. S. Whitefield, C. J. Wei, and J. C. Hwang 31 May 1993 29 p
(Grant AF-AFOSR-0302-90)
(AD-A266184; AFOSR-93-0438TR) Avail: CASI HC A03/MF A01

The high power operation of the heterojunction bipolar transistor (HBT) has been analyzed by experimentally determining the junction temperature and separating temperature effects from other high power effects. In addition, an HBT large signal model has been developed that is valid for the linear, saturation, and cutoff regions, with low frequency temperature effects included. This model has been implemented in a commercial harmonic balance simulator, LIBRA from EEsof, making it particularly suitable for the design and simulation of HBT microwave power integrated circuits. In addition, an analysis of the most temperature-sensitive microwave elements for the HBT has been performed using measured s-parameter data at five elevated temperatures from 23 C to 226 C. The element values were compared to a physical model showing excellent agreement in magnitude and direction of change with temperature and bias. The transistor cutoff frequencies were also measured and calculated, showing a monotonic decrease with temperature of approximately 50% over the 200 C range. DTIC

STRAY INSENSITIVE SWITCHED CAPACITOR COMPOSITE OPERATIONAL AMPLIFIERS M.S. Thesis
Eldon W. Bingham Mar. 1993 177 p
(AD-A267412) Avail: CASI HC A09/MF A02

In this research, analog active circuits are designed combining the properties of switched capacitors and composite operational amplifiers. This combined design improves upon the single operational amplifier's finite dc gain, smaller bandwidth, lower slew rate, finite input impedance, and less than ideal output performance. The switched capacitor is implemented using both the toggle switch capacitor and the modified open circuit floating resistor techniques. The composite operational amplifier is implemented using the C2OA-1 and C2OA-2 designs from the CNOA-1 possibilities. These four designs are evaluated in a finite-gain circuit and their results are compared with the results obtained from the continuous circuits of the same design. DTIC

SURFACE FLASHOVER OF SEMICONDUCTORS: A FUNDAMENTAL STUDY Final Report, 15 Jan. 1989 - 14 Jan. 1993
P. F. Williams and W. C. Nunnally 16 Jun. 1993 40 p
(Grant AF-AFOSR-0253-89)
(AD-A267382; AFOSR-93-0481TR) Avail: CASI HC A03/MF A01

This report presents research results and activities carried out during the period 15 Jan. 1989 through 14 Jan. 1993 sponsored by AFOSR Grant No. AFOSR-89-0253. Work was carried out at the University of Nebraska (UNL) and at the University of Texas at Arlington (UTA). The work at each of these locations is discussed in detail in separate sections of this report. Important conclusions are as follows: (1) the phenomenon commonly referred to as surface flashover in silicon results from a sequence of events occurring primarily inside the silicon, rather than in the ambient surrounding it; (2) current filamentation plays an important role in the breakdown process; (3) contacts to the silicon influence the breakdown process; (4) the condition of the sample surface strongly influences breakdown; (5) flashover can be inhibited through the action of weak visible or near infra-red illumination; (6) current before the initiation of flashover is strongly space-charge limited; and (7) double injection effects are clearly present in p+-i-n+ structures, and will limit the applicability of such structures as photoconductive switches. (Contract N00014-92-J-1720)
(AD-A267877) Avail: CASI HC A03

GaN and AlN have been deposited on sapphire and SiC using gas-source MBE and extensively investigated via high resolution TEM. Below the critical thickness, AlN only contains threading dislocations emanating from the misfit dislocations; above this thickness, defects parallel to the growth surface greatly increase. The defect density of AlN grown on SiC at 1100 C is much lower than that contained in material deposited at 700 C. Deposition of GaN on sapphire or SiC results in a larger number of threading dislocations caused by the large misfit as well as a high concentration of dislocations parallel to the growth surface. Both types of defects are decreased in density if the GaN is deposited on AlN. Monocrystalline GaN thin films have also been deposited via layer-by-layer deposition on SiC(0001) substrates from triethylgallium and ammonia. Source concentrations of Ga and exposure times strongly affect the growth process. The near surface region of monocrystalline BP has been converted to BN via exposure to atomic N produced from N2 in an ECR source, as proven by XPS measurements. Current-voltage measurements show an increase in resistance by a factor of 40 after the conversion. Development of (1) ohmic and rectifying contacts, (2) facilities for reactive ion etching, and (3) a photo- and cathodoluminescence system are also underway. DTIC

AN ELECTROACOUSTIC TRANSDUCER FOR PURPOSES OF PHOTOACOUSTIC SPECTROSCOPY [PRZETWORNIK ELEKTROAKUSTYCZNY DO CELOW SPEKTROSKOPII FOTOAKUSTYCZNEJ]

Henryk Makowski, Wladyslaw Opydo, Jerzy Ranachowski, and Jadwiga Rzeszotarska 1992 12 p In POLISH

(IFTR-7/1992) Avail: CASI HC A03/MF A01

Requirements that must be satisfied by a broadband converter that converts acoustic signals into electric signals in a photoacoustic spectroscope chamber are given. An electroacoustic transducer that satisfies these requirements was developed and fabricated based on the commercially manufactured MS 52 microphone at the TONSIL Joint Stock Company in Wrzesien. Compared to the MS 52 microphone, the fabricated transducer prototypes have ten times greater efficiency (45 mV/Pa), a superior transmission range of 10-1000 Hz for a nonuniformity of 1 dB and 10-50,000 Hz for a nonuniformity of 2 dB. Tests on the application of the electroacoustic transducer prototypes in photoacoustic spectroscopy confirmed their suitability. Transl. by FLS

A MODIFIED TWO-FLUID MODEL OF CONDUCTIVITY FOR SUPERCONDUCTING SURFACE RESISTANCE CALCULATION M.S. Thesis

Derek S. Linden May 1993 135 p

(AD-A267549; AFIT/CI/CIA-93-077) Avail: CASI HC A07/MF A02

The traditional two-fluid model of superconducting conductivity was modified to make it accurate, while remaining fast, for designing and simulating microwave devices. The modification reflects the BCS coherence effects in the conductivity of a superconductor and is incorporated through the ratio of normal to superconducting electrons. This modified ratio is a simple analytical expression which depends on frequency, temperature, and material parameters. This modified two-fluid model allows accurate and rapid calculation of the microwave surface impedance of a superconductor in the clean and dirty limits and in the weak- and strong-coupled regimes. The model compares well with surface resistance data for Nb and provides insight into Nb3Sn and YBa2Cu3O(7-delta). Numerical calculations with the modified two-fluid model are an order of magnitude faster than the quasi-classical program by Zimmermann and two to five orders of magnitude faster than Halbritter's BCS program for surface resistance. LATTICE-MISMATCHED In(0.40)Al(0.60)As WINDOW LAYERS FOR INDIUM PHOSPHIDE SOLAR CELLS

Raj K. Jain (National Academy of Sciences - National Research Council, Washington, DC.), Geoffrey A. Landis (Sverdrup Technology, Inc., Brook Park, OH.), David M. Wilt, and Dennis J. Flood Nov. 1993 11 p Presented at the 23rd Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993; sponsored by IEEE

(Contract NAS3-25266; RTOP 506-41-11)

(NASA-TM-106255; E-7879; NAS 1.15:106255) Avail: CASI HC A03/MF A01

The efficiency of indium phosphide (InP) solar cells is limited by its high surface recombination velocity (approximately 10(exp 7) cm/s). This might be reduced by a wide-bandgap window layer. The performance of InP solar cells with wide-bandgap (1.8 eV) lattice-mismatched In(0.40)Al(0.60)As as a window layer was calculated. Because the required window layer thickness is less than the critical layer thickness, growth of strained (pseudomorphic) layers without interfacial misfit dislocations should be possible. Calculations using the PC-ID numerical code showed that the efficiencies of baseline and optimized p(+)n (p-on-n) cells are increased to more than 22 and 24 percent, (air mass zero (AMO), 25 C), respectively for a lattice-mismatched In(0.40)Al(0.60)As window layer of 10-nm thickness. Currently, most cell development work has been focused on n(+)p (n-on-p) structures although comparatively little improvement has been found for n(+)p cells. Author (revised)

INVESTIGATION OF THE ENERGY DISTRIBUTION OF IONS, STRIKING THE CATHODE IN AN ABNORMAL GLOW DISCHARGE

A. A. Gurin, K. L. Kruglikov, A. Yu. Pankin, and V. M. Slobodyan 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-623987; KIYaI-92-17) Avail: CASI HC A03 (US Sales Only)

The energy spectrum of ions at the cathode in an abnormal glow discharge has been investigated for gases H2, D2, He, and Ar at discharge current densities j(sub a) approximately greater than 10mA/sq cm and gas pressures p approximately greater than 1 Torr. It is shown that ion energy distribution is spread up to cathode fall voltages V(sub c); most of the particles in the ion stream have energies not higher than (0,1-0,3)(sub 2)V(sub c). It is found that with rising of the value j/p(sup 2) the low energy portion of the spectrum is transferred from the gradually decaying curve to one having low-energy peak. It is supposed that this phenomenon is due to peculiarities of space distribution of electron ionization intensity in dark cathode space. DOE

Pegasus II is the upgraded version of Pegasus, a pulsed power machine used in the Los Alamos AGEX (Above Ground Experiments) program. A goal of the program is to produce an intense (greater than 100 TW) source of soft x-rays from the thermalization of the kinetic energy of a 1 to 10 MJ plasma implosion. The radiation pulse should have a maximum duration of several 10's of nanoseconds and will be used in the study of fusion conditions and material properties. The radiating plasma source will be generated by the thermalization of the kinetic energy of an imploding cylindrical, thin, metallic foil. This paper addresses experiments done on a capacitor bank to develop a switch (plasma flow switch) to switch the bank current into the load at peak current. This allows efficient coupling of bank energy into foil kinetic energy. DOE

LEAK DETECTION UTILIZING ANALOG BINAURAL (VLSI) TECHNIQUES Patent Application

Frank T. Hartley, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 18 Aug. 1993 23 p

(Contract NAS7-918)

(NASA-Case-NPO-18399-1-CU; NAS 1.71:NPO-18399-1-CU; US-Patent-Appl-SN-111317) Avail: CASI HC A03/MF A01

A detection method and system utilizing silicon models of the traveling wave structure of the human cochlea to spatially and temporally locate a specific sound source in the presence of high noise pandemonium is presented. The detection system combines two-dimensional stereausis representations, which are output by at least three VLSI binaural hearing chips, to generate a three-dimensional stereausis representation including both binaural and spectral information which is then used to locate the sound source. NASA

OPTICALLY-SWITCHED SUBMILLIMETER-WAVE OSCILLATOR AND RADIATOR Patent Application

Michael G. Spencer, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and Joseph Maserjian, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 23 Sep. 1993 29 p

(Contract NAS7-918)

(NASA-Case-NPO-18547-1-CU; NAS 1.71:NPO-18547-1-CU; US-Patent-Appl-SN-125966) Avail: CASI HC A03/MF A01

A submillimeter wave-generating integrated circuit includes an array of N photoconductive switches biased across a common voltage source and an optical path difference from a common optical pulse of repetition rate f sub 0 providing a different optical delay to each of the switches. In one embodiment, each incoming pulse is applied to successive ones of the N switches with successive delays. The N switches are spaced apart with a suitable switch-to-switch spacing so as to generate at the output load or antenna radiation of a submillimeter wave frequency f on the order of Nf sub 0. Preferably, the optical pulse has a repetition rate of at least 10 GHz and N is of the order of 100, so that the circuit generates radiation of frequency of the order of or greater than 1 Terahertz. HIGH-SPEED NONLINEAR SWITCHING MECHANISMS AND DEVICES FOR MULTI-GIGABIT DATA PROCESSING Final Report, Feb. 1992 - Feb. 1993

N. Peyghambarian, S. Johns, M. Krol, R. Boncek, and J. Stacy May 1993 14 p

(Contract F30602-92-C-0020)

(AD-A267753; RL-TR-93-92) Avail: CASI HC A03/MF A01

A high contract, low intensity GaAlInAs/AlInAs multiple quantum well asymmetric Fabry-Perot reflection modulator for operation at 1.3 microns has been demonstrated. The reflection modulator takes advantage of the large absorptive and refractive nonlinearities associated with saturating the heavy-hole exciton resonance. We achieve an on/off contrast ratio in excess of 1000:1 (30 dB) and an insertion loss of 2.2 dB at a pump intensity of 30 kW/cm(exp 2), corresponding to a carrier density of 4.5 x 10(exp 17) cm(exp -3). The modulator was demonstrated to have a large operating bandwidth achieving an on/off contrast ratio of greater than 100:1 over a 5 nm optical band. The operating speed of the modulator was measured and found to approach 1 GHz. DTIC

OSA PROCEEDINGS ON ULTRAFAST ELECTRONICS AND OPTOELECTRONICS, VOLUME 14

Jagdeep Shah, ed. and Umesh Mishra, ed. 27 Jan. 1993 264 p Meeting held in San Francisco, CA, 25-27 Jan. 1993 Sponsored by AFOSR

(AD-A267972; AFOSR-93-0639TR-Vol-14) Avail: CASI HC A12/MF A03

This volume is comprised of papers that were presented at the Fifth Topical Meeting on Ultrafast Electronics and Optoelectronic, held in San Francisco, January 23-25, 1993. The purpose of this topical meeting, since its inception in 1985, has been to foster greater interaction between researchers in the electronics and optoelectronics communities who share a common interest in the physics and technology of ultrafast electronics and optoelectronic devices, their multigigahertz applications, and ultrafast measurement techniques. The number of abstracts submitted to this meeting was considerably larger than for the previous meetings, indicating the appeal of this interdisciplinary approach and the grow in importance of this field. The topics are ultrafast optoelectronic devices, high speed electronic devices, terahertz transients, physics of semiconductors, novel sources and techniques, (sub)millimeter wave devices, photoconductive and electro-optic sampling, and superconductors. BASIC OPTICAL STUDIES OF HIGH T(c) OXIDE SUPERCONDUCTORS Final Report, 15 Jan. 1990 - 14 Jan. 1993

M. S. Dresselhaus and G. Dresselhaus 15 Jun. 1993 9 p

(Grant AF-AFOSR-0123-90)

(AD-A268148; AFOSR-93-0584TR) Avail: CASI HC A02/MF A01

During the 1992-93 year of the research program on Basic Optical Studies of High T(sub c) Oxide Superconductors, the effort was focused on a number of projects. The collaborative study of the microwave properties of superconductors with researchers at Rome Labs and the MIT Lincoln Laboratory continued and significant results were obtained on the microwave behavior in the non-linear high rf power regime for YBa2Cu3O(7-x) and this work will be a major part of the Ph.D. thesis of Paul Nguyen. During this year we continued study of the effect of halogen doping on the restoration of superconductivity to YBCO samples previously deoxygenated and hence rendered non-superconducting. Extensive progress was also made on our new effort in studying superconductivity and the associated phonon spectra and electron-phonon interaction in the alkali metal doped C60 materials. We review in this report the progress that was made on each of these projects, referring to the publications that were prepared on each of the topics under investigation. DTIC

FSM TEST: A FUNCTIONAL TEST GENERATION SYSTEM FOR SEQUENTIAL CIRCUITS

Franco Fummi Mar. 1993 32 p
(Rept-93-017; ETN-93-94569) Avail: Issuing Activity (Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milan, Italy)

An approach to test pattern generation for Finite State Machines (FSM's) and the relationships with their gate level implementation is presented. The algorithm is based on a functional fault model. A restricted set of transitions of the FSM is analyzed and particular state distinguishing sequences (EUIO's) are adopted to observe their final state. Overlapping and concatenation of test sequences is performed in order to reduce test length. Test length obtained is in most cases shorter than previously published functional approaches and the CPU (Central Processing Unit) time requirements are very low in comparison with the gate level ATPG's. Some polynomial complexity preserving techniques are introduced in order to improve the final fault coverage. A number of experiments on MCNC benchmarks have shown the effectiveness of the test algorithm both at the functional level and at the gate level, where the coverage of single stuck-at faults in most cases achieves 100. FIELD-EMITTER ARRAYS FOR RF VACUUM MICROELECTRONICS Quarterly Report No. 7, 1 Apr. - 31 Jun. 1993
C. A. Spindt, A. Rosengreen, and P. R. Schwoebel 9 Aug. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MDA972-91-C-0029; ARPA Order 8162; SRI Proj. 2743)
(AD-A268397) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

SRI International has completed the seventh quarter of a program to develop field-emitter arrays for vacuum microelectronics. We have met the first-phase program goals of 5 mA total emission, with a current density of 5 A/sq cm for at least 2 hours and demonstrated modulation of the emission current at a frequency of 1 GHz. A series of controlled tests with photoresist/developer/stripper combinations continued, and sulfur hexafluoride was identified as the source of a contamination problem in the low-capacitance cathode fabrication technology. The active area of the low-capacitance cathode was shielded from the base electrode to eliminate excessive gate interception of the emitter. The effects of processing on cathode performance were studied through experiments with hydrogen plasma treatment. Four cathodes were set up in a high-frequency chamber in an effort to gain data on the effectiveness of shielding the electrode. DTIC

Power Integrated Circuits (PIC) is one of the most rapidly growing branches of the semiconductor technology. The PIC markets has been forecast to grow from 660 million dollars in 1990 to 1658 million dollars in 1994. It has even been forecast that at the end of the 1990's the PIC markets would correspond to the value of the whole semiconductor production in 1990. Automotive electronics will play the leading role in the development of the standard PIC's. Integrated motor drivers (36 V/4 A), smart integrated switches (60 V/30 A), solenoid drivers, integrated switch-mode power supplies and regulators are the latest standard devices of the PIC manufactures. ASIC (Application Specific Integrated Circuits) PIC solutions are needed for the same reasons as other ASIC devices: there are no proper standard devices, a company has a lot of application knowhow, which should be kept inside the company, the size of the product must be reduced, and assembly costs are wished to be reduced by decreasing the number of discrete devices. During the next few years the most probable ASIC PIC applications in Finland will be integrated solenoid and motor drivers, an integrated electronic lamp ballast circuit and various sensor interface circuits. Application of the PIC technologies to machines and actuators will strongly be increased all over the world. This means that various PIC's, either standard PIC's or full custom ASIC circuits, will appear in many products which compete with the corresponding Finnish products. Therefore the development of the PIC technologies must be followed carefully in order to immediately be able to apply the latest development in the smart power technologies and their design methods. IN-SITU ELECTRON AND OPTICAL SPECTROSCOPIES OF TRANSLATIONAL AND VIBRATIONAL ACTIVATED BOND BREAKING AND FORMATION ON SEMICONDUCTORS Annual Report, 1 Jun. 1992 - 31 May 1993
Wilson Ho 26 Jul. 1993 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-J-0309)
(AD-A268192; AFOSR-93-0595TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This experimental research program seeks a basic understanding of the growth and processing of materials on semiconductor surfaces. Interactions of molecules with surfaces are investigated by varying the translational and vibrational energies of the impinging molecules from a molecular beam and probing the resulting species on the surface by in-situ time resolved electron energy loss spectroscopy, second harmonic generation, and two-photon photoemission. The reactions of H2, CO, CO2, CH(x)F(4-x) (where x = 0-4), and CH3Cl on Si(100)2x1 were studied in order to understand the chemistry of group 4 elements: C, Si, and Ge. These studies will be extended to Ge2H6 and Si(111)7x7. The nature of bond breaking and formation of Ge and C on Si to form Ge/Si, SiC, and diamond will be investigated. DTIC

ELECTRICAL PROPERTIES OF SOL-GEL PZT THIN FILMS FOR DECOUPLING CAPACITOR APPLICATIONS
R. W. Schwartz, D. Dimos, S. J. Lockwood, and V. M. Torres 1992 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-016491; SAND-92-2907C; CONF-930405-28) Avail: CASI HC A02/MF A01

The successful development of PZT thin films for decoupling capacitor devices places stringent requirements on the dielectric and leakage

properties of the films. The authors have characterized these properties for PZT thin films with compositions near the morphotropic phase boundary prepared by a sol-gel process. Capacitors were fabricated from films with thicknesses varying from 0.4 to 1.2 (mu)m. For zero applied bias, the dielectric constants of these films were in the range of 800 to 1200. The room temperature dielectric constant was observed to decrease by approximately 25% with the application of a 5 V bias. They have also characterized the interrelationships between temperature, applied bias, and dielectric constant. The capacitors exhibited asymmetry in their leakage and breakdown characteristics with bias sign, as well as non-linear I-V behavior. Breakdown fields for undoped PZT 53/47 films were typically in the range of 750 kV/cm. They have also studied the effects of La and Nb donor doping on the leakage behavior of PZT 50/50 thin films. Doping with 2 to 5 mol % of either La or Nb resulted in a reduction in film leakage current by a factor of 10(sup 3). Leakage currents of the highly doped materials were approximately 2 (times) 10(sup (minus)9) A/cm(sup 2) under an applied field of approximately 65 kV/cm at a temperature of 125 C. DOE

FIELD INVESTIGATION OF THE RELATIONSHIP BETWEEN BATTERY SIZE AND PV SYSTEM PERFORMANCE
J. Stevens, J. Kratochvil, and S. Harrington (Ktech Corp., Albuquerque, NM.) 1993 7 p Presented at the 23rd Institute of Electrical and Electronics Engineers (IEEE) Photovoltaic Specialits Conference, Louisville, KY, 10-14 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-016503; SAND-93-1255C; CONF-930540-10) Avail: CASI HC A02/MF A01

Four photovoltaic-powered lighting systems were installed in a National Forest Service campground in June of 1991. These systems have identical arrays, loads and charge controllers. The only difference was in the rated capacity of the battery bank for each system. The battery banks all use the same basic battery as a building block with the four systems utilizing either one battery, two batteries, three batteries or four batteries. The purpose of the experiment is to examine the effect of the various battery sizes on the ability of the system to charge the battery, energy available to the load, and battery lifetime. Results show an important trend in system performance concerning the impact of charge controllers on the relation between array size and battery size which results in an inability to achieve the days of battery storage originally designed for. ON THE RECEPTIVITY PROBLEM FOR 0(1) WAVELENGTH GOERTLER VORTICES Final Report
Andrew P. Bassom (Exeter Univ., England.) and Philip Hall (Manchester Univ., England.) Aug. 1993 25 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191519; NAS 1.26:191519; ICASE-93-58) Avail: CASI HC A03/MF A01

In this paper, we make an investigation of the receptivity of boundary layer flows to Gortler vortex modes. A study by Denier, Hall, and Seddougui (1991) of the generation of vortices by wall roughness elements concluded that such elements are extremely poor as mechanisms to stimulate short wavelength modes, but that analysis was in error. We re-examine this problem and demonstrate how the form of the wall roughness is crucial in determining the vortex stability characteristics downstream of the roughness. In particular, we investigate the cases of both isolated and distributed forcing functions and show that, in general, a distributed function is much more important in generating vortices than are either isolated roughness or freestream disturbances. COAXIAL AIRBLAST ATOMIZERS Final Report, 3 Apr. 1991 - 3 Apr. 1993
Y. Hardalupas and J. H. Whitelaw May 1993 203 p Prepared in cooperation with Scientific Research Associates, Inc., Glastonbury, CT
(Contract NAS8-38872)
(NASA-CR-193845; NAS 1.26:193845; SRA-R93-9083-F) Avail: CASI HC A10/MF A03

An experimental investigation was performed to quantify the characteristics of the sprays of coaxial injectors with particular emphasis on those aspects relevant to the performance of rocket engines. Measurements for coaxial air blast atomizers were obtained using air to represent the gaseous stream and water to represent the liquid stream. A wide range of flow conditions were examined for sprays with and without swirl for gaseous streams. The parameters varied include Weber number, gas flow rate, liquid flow rate, swirl, and nozzle geometry. Measurements were made with a phase Doppler velocimeter. Major conclusions of the study focused upon droplet size as a function of Weber number, effect of gas flow rate on atomization and spray spread, effect of nozzle geometry on atomization and spread, effect of swirl on atomization, spread, jet recirculation and breakup, and secondary atomization. ADVANCED METHODS FOR CASCADE TESTING [METHODES AVANCEES POUR LES ESSAIS DES GRILLES D'AUBES]
Charles Hirsch, ed. (Vrije Univ., Brussels, Belgium.) Aug. 1993 196 p
(AGARD-AG-328; ISBN-92-835-0717-7) Copyright Avail: CASI HC A09/MF A03

Considerable advances have been achieved over the last decennia in the field of cascade testing, but they were generally not reported in sufficient detail. As an example, details of transonic/supersonic cascade testing procedures were scarcely documented in literature. Many other aspects evolved considerably, originally from the progress of experimental techniques as well as from the interaction with computer data. New methodologies based on advanced instrumentation gained sufficient validation. Consequently, the Propulsion and Energetics Panel decided to initiate an AGARDograph on this subject in 1988. Since then, several authors prepared chapters for the AGARDograph, coordinated by the editor. The following chapters are included: Modeling Turbomachinery Flow Conditions, Linear Cascades, Annular Cascades, Aspects of Hot Cascades, Transient Cascade Testing, Unsteady Flow in Cascades, and 3-D Laser Anemometry in Annular Cascades. [LARGE-EDDY SIMULATIONS (LES) OF FLOWS AND TURBULENCE DISTRIBUTION] Final Report, 15 Jan. 1990 - 30 Sep. 1992
Steven A. Orszag 5 Mar. 1993 14 p
(Grant AF-AFOSR-0124-90)
(AD-A267182; AFOSR-93-0472TR) Avail: CASI HC A03/MF A01

This report summarizes results published with support of this grant on renormalization group methods for large-eddy simulations (LES) of fluid flows, studies of the fundamental dynamics of compressible turbulence, development of methods to study strongly interacting vortices, methods to study intermittent probability distributions in turbulence, and studies of dynamical issues involved in intermittent turbulence. Publications from 31 papers and 2 book chapters are summarized. The results demonstrate the utility of LES techniques, the differences between incompressible and compressible turbulence, and advanced models for small-scale structure that lead a series of surprising results, including a two-fluid model for small-scales in high Reynolds number turbulence. TOLLMIEN-SCHLICHTING/VORTEX INTERACTIONS IN COMPRESSIBLE BOUNDARY LAYER FLOWS Final Report

Nicholas D. Blackaby (Manchester Univ., England.) Aug. 1993 36 p Submitted for publication

(Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191515; NAS 1.26:191515; ICASE-93-55) Avail: CASI HC A03/MF A01

The weakly nonlinear interaction of oblique Tollmien-Schlichting waves and longitudinal vortices in compressible, high Reynolds number, boundary-layer flow over a flat plate is considered for all ranges of the Mach number. The interaction equations comprise of equations for the vortex which is indirectly forced by the waves via a boundary condition, whereas a vortex term appears in the amplitude equation for the wave pressure. The downstream solution properties of interaction equations are found to depend on the sign of an interaction coefficient. Compressibility is found to have a significant effect on the interaction properties; principally through its impact on the waves and their governing mechanism, the triple-deck structure. It is found that, in general, the flow quantities will grow slowly with increasing downstream co-ordinate; i.e. in general, solutions do not terminate in abrupt, finite-distance 'break-ups'. Author

SPECIAL COURSE ON SHOCK-WAVE/BOUNDARY-LAYER INTERACTIONS IN SUPERSONIC AND HYPERSONIC FLOWS [INTERACTIONS ENTRE ONDES DE CHOC ET COUCHES LIMITES DANS LES ECOULEMENTS SUPERSONIQUES ET HYPERSONIQUES]

Aug. 1993 298 p Course held in Rhode-Saint-Genese, Belgium, 24-28 May 1993; sponsored by VKI Original contains color illustrations

(AGARD-R-792; ISBN-92-835-0718-5) Copyright Avail: CASI HC A13/MF A03

Notes for the AGARD Fluid Dynamics Panel (FDP) Special Course on 'Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows' are presented. The objective was to report on results from recent research programs providing a consolidated review of these activities and a sound basis for developing more reliable methodologies for future vehicle design. The course also provided a focused review of recent progress for swept interactions in both laminar and turbulent flows, including discussions: flowfield structure; scaling and similarity laws; effect of shock strength on flow feature; effect of shock generator geometry for a given shock strength; techniques for investigating swept interactions, particularly optical techniques; and contributions of numerical simulations to the understanding of swept interactions. The effects of turbulence and turbulence modeling on the flowfields are provided. For individual titles, see N94-15197 through N94-15203.

SWEPT SHOCK/BOUNDARY-LAYER INTERACTIONS: SCALING LAWS, FLOWFIELD STRUCTURE, AND EXPERIMENTAL METHODS

Gary S. Settles *In* AGARD, Special Course on Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows Aug. 1993 40 p Sponsored by NASA. Ames Research Center and AFOSR (For primary document see N94-15196 03-34)

Copyright Avail: CASI HC A03/MF A03

A general review is given of several decades of research on the scaling laws and flowfield structures of swept shock wave/turbulent boundary layer interactions. Attention is further restricted to the experimental study and physical understanding of the steady-state aspects of these flows. The interaction produced by a sharp, upright fin mounted on a flat plate is taken as an archetype. An overall framework of quasiconical symmetry describing such interactions is first developed. Boundary-layer separation, the interaction footprint, Mach number scaling, and Reynolds number scaling are then considered, followed by a discussion of the quasiconical similarity of interactions produced by geometrically-dissimilar shock generators. The detailed structure of these interaction flowfields is next reviewed, and is illustrated by both qualitative visualizations and quantitative flow images in the quasiconical framework. Finally, the experimental techniques used to investigate such flows are reviewed, with emphasis on modern non-intrusive optical flow diagnostics. Author

SWEPT SHOCK WAVE/LAMINAR BOUNDARY LAYER INTERACTIONS, EXPERIMENTAL, AND NUMERICAL RESULTS

G. Degrez *In* AGARD, Special Course on Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows Aug. 1993 19 p (For primary document see N94-15196 03-34)

(Contract Aero-0027-C)

Copyright Avail: CASI HC A03/MF A03

Experimental and numerical investigations of swept shock wave/laminar boundary layer interactions are reviewed. Experimental investigations show that the flowfield is characterized by an extensive primary separation of the boundary layer upstream of the inviscid shock wave, which then rolls up into a very elongated vortex. This is often accompanied by secondary and sometimes higher order separations. Similar to turbulent interactions, the flowfield is essentially conical as far as the surface flow data are concerned (surface pressures, heat transfer, and skin friction patterns). Also, the free-interaction concept introduced for turbulent interactions is shown to apply to laminar interactions as well. Recent LDV flowfield data for a supersonic interaction are presented. They nicely confirm the vortical structure of the interaction deduced from the surface data as well as the important thickening of the viscous layer due to separation. They also show that the vertical dimension of the interaction does not obey a conical similarity rule but rather follows the classical boundary layer scaling. Numerical investigations confirm these experimental findings. None of these was however carried out with sufficient grid resolution so as to demonstrate grid convergence and code validity, in particular concerning the location of separation lines. NUMERICAL SIMULATION OF 3-D SHOCK WAVE TURBULENT BOUNDARY LAYER INTERACTIONS

Doyle D. Knight *In* AGARD, Special Course on Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows Aug. 1993 32 p (For primary document see N94-15196 03-34)

(Contract F49620-93-1-0005)

Copyright Avail: CASI HC A03/MF A03

The capability for numerical simulation of 3-D shock wave turbulent boundary layer interactions is assessed. Specific configurations examined include the sharp fin, blunt fin, cylinder/flare, swept compression corner and crossing shock. Future needs in improved computational methods, collaborative experimental/computational efforts and incorporation of knowledge of flowfield structure into more effective designs are discussed. UNSTEADY PHENOMENA IN SHOCK WAVE/BOUNDARY LAYER INTERACTION

D. S. Dolling *In* AGARD, Special Course on Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows Aug. 1993 46 p Sponsored by NASA. Lewis Research Center; NASA. Langley Research Center; ARO; and AFOSR (For primary document see N94-15196 03-34)

Copyright Avail: CASI HC A03/MF A03

A brief review is given of the unsteadiness of shock wave/turbulent boundary layer interaction. The focus is on interactions generated by swept and unswept compression ramps, by flares, steps and incident shock waves, by cylinders and blunt fins, and by glancing shock waves. The effects of Mach number, Reynolds number, and separated flow scale are discussed as are the physical causes of the unsteadiness. The implications that the unsteadiness has for interpreting time-average surface and flowfield data, and for comparisons of such experimental data with computation, is also briefly discussed. Finally, some suggestions for future work are given. It is clear that there are large gaps in the data base and that many aspects of such phenomena are poorly understood. Much work remains to be done. Author

With the advent of Laser Doppler Velocimetry (LDV) in the 1970's, it became possible to investigate high speed complex flows containing shock waves, separated regions, and strong turbulent fluctuations. This powerful tool has allowed an unprecedented physical description of the flow fields resulting from shock wave/boundary layer interaction, both in two- and three-dimensional flows. It is remarkable that the development of LDV accompanied the progress in CFD, thus permitting an in depth validation of the theoretical models. The Lecture focusses on the use of LDV to investigate typical transonic and supersonic interactions occurring, firstly in nominally 2D configurations, then in a 3D channel flow. The data thus obtained are used to validate a detailed description of the flow field and to validate several equilibrium and non-equilibrium turbulence models. In 2D flows, the calculations were executed by using an economical boundary layer type approach, for the 3D case the models were implemented in a Navier-Stokes code. Author (revised)

Since the pioneering theory of Boussinesq and the first application indicated by Prandtl, turbulence modeling has been continuously improved in order to allow effective prediction of turbulent flows. Since these early contributions, various methodologies were worked out to account properly for 'complex' effects on turbulence. Among others, these 'complex' effects are caused by curvature, body forces (gravitation or magnetic fields), unsteadiness, and variable density. In fact, in real flows situations, it is often difficult to separate these effects, and the prediction of a flow configuration of industrial interest must always combine the simultaneous treatment of several effects. Depending on the application domain, some effects can be considered as dominant which allows neglect of others completely. As an example, geophysical flows in oceans are dominated by stratification and rotation, while compressibility or solid boundary effects can be neglected. In contrast, flows around an aircraft fuselage in real flight conditions are strongly influenced by compressibility and wall effects and not at all by gravitation or rotation. Because of the requirements imposed by a wide variety of industrial and aeronautical problems, one of the biggest challenges, during the last few years in the field of turbulence modeling was the correct accountability of the variable density effects. Variable density can have different origins, which can result for instance from: (1) the mixture of gases with different density; (2) a temperature gradient within an homogeneous fluid; (3) compressibility in high speed flows; or (4) reactive flows (for instance flames, chemical or gasdynamic laser flows). Unfortunately, until now, only a small fraction of the modeling effort has been devoted to these flows. Author

HYPERSONIC SHOCK WAVE BOUNDARY LAYER INTERACTIONS OVER SIMPLIFIED DEFLECTED CONTROL SURFACE CONFIGURATIONS

G. Simeonides *In* AGARD, Special Course on Shock-Wave/Boundary-Layer Interactions in Supersonic and Hypersonic Flows Aug. 1993 47 p Sponsored in part by Dassault Aviation Original contains color illustrations (For primary document see N94-15196 03-34)

Copyright Avail: CASI HC A03/MF A03

The problem of hypersonic shock wave boundary layer interactions over simplified geometric configurations that simulate the vicinity of deflected control surfaces on lifting reentry vehicles is addressed. The discussion evolves primarily around surface pressure and heat transfer data over flat plate/two-dimensional and swept compression ramp configurations, and the axisymmetric hyperboloid/flare configuration, emphasizing the prediction of peak heating in regions of interaction, the promotion of laminar-turbulent transition, and the performance and validation of CFD codes. Following a brief overview of the fundamental physical phenomena associated with shock wave boundary layer interactions, as these have been identified and summarized in the extensive literature available on the subject, the paper is split into three main parts. The first part concentrates on the analysis of global pressure and heat transfer distributions and their comparison with simple boundary layer theory, emphasizing peak heating at the downstream end of the interaction region. The second part addresses the formation of streamwise striations in reattaching flow regions, and the associated spanwise heat transfer variations which may exceed plus or minus 50 percent of the mean local heating level. Last but not least, the performance and limitations of state-of-the-art Navier-Stokes computations in computing hypersonic separated flows are illustrated by means of a series of computational fluid dynamics (CFD) code validation test cases assembled in recent years. DSMC SIMULATIONS OF MACH 20 NITROGEN FLOWS ABOUT A 70 DEGREE BLUNTED CONE AND ITS WAKE

James N. Moss, Virendra K. Dogra (Vigyan Research Associates, Inc., Hampton, VA.), and Richard G. Wilmoth Aug. 1993 157 p (RTOP 506-40-91-03)

(NASA-TM-107762; NAS 1.15:107762) Avail: CASI HC A08/MF A02

Numerical results obtained with the direct simulation Monte Carlo (DSMC) method are presented for Mach 20 nitrogen flow about a 70-deg blunted cone. The flow conditions simulated are those that can be obtained in existing low-density hypersonic wind tunnels. Three sets of flow conditions are simulated with freestream Knudsen numbers ranging from 0.03 to 0.001. The focus is to characterize the wake flow under rarefied conditions. This is accomplished by calculating the influence of rarefaction on wake structure along with the impact that an afterbody has on flow features. This data report presents extensive information concerning flowfield features and surface quantities. Author

LARGE EDDY SIMULATION AND DIRECT NUMERICAL SIMULATION OF HIGH SPEED TURBULENT REACTING FLOWS Semiannual Report, 1 Feb. - 31 Oct. 1993

V. Adumitroaie, S. H. Frankel (Purdue Univ., West Lafayette, IN.), C. K. Madnia, and P. Givi 1993 232 p

(Contract NAG1-1122; N00014-90-J-1403; NSF CTS-92-53488)

(NASA-CR-193131; NAS 1.26:193131) Avail: CASI HC A11/MF A03

The objective of this research is to make use of Large Eddy Simulation

(LES) and Direct Numerical Simulation (DNS) for the computational analyses of high speed reacting flows. Our efforts in the first phase of this research conducted within the past three years have been directed in several issues pertaining to intricate physics of turbulent reacting flows. In our previous 5 semi-annual reports submitted to NASA LaRC, as well as several technical papers in archival journals, the results of our investigations have been fully described. In this progress report which is different in format as compared to our previous documents, we focus only on the issue of LES. The reason for doing so is that LES is the primary issue of interest to our Technical Monitor and that our other findings were needed to support the activities conducted under this prime issue. The outcomes of our related investigations, nevertheless, are included in the appendices accompanying this report. The relevance of the materials in these appendices are, therefore, discussed only briefly within the body of the report. Here, results are presented of a priori and a posterior analyses for validity assessments of assumed Probability Density Function (PDF) methods as potential subgrid scale (SGS) closures for LES of turbulent reacting flows. Simple non-premixed reacting systems involving an isothermal reaction of the type A + B yields Products under both chemical equilibrium and non-equilibrium conditions are considered. A priori analyses are conducted of a homogeneous box flow, and a spatially developing planar mixing layer to investigate the performance of the Pearson Family of PDF's as SGS models. A posteriori analyses are conducted of the mixing layer using a hybrid one-equation Smagorinsky/PDF SGS closure. The Smagorinsky closure augmented by the solution of the subgrid turbulent kinetic energy (TKE) equation is employed to account for hydrodynamic fluctuations, and the PDF is employed for modeling the effects of scalar fluctuations. The implementation of the model requires the knowledge of the local values of the first two SGS moments. These are provided by additional modeled transport equations. In both a priori and a posteriori analyses, the predicted results are appraised by comparison with subgrid averaged results generated by DNS. Based on these results, the paths to be followed in future investigations are identified. Author

PROTEUS TWO-DIMENSIONAL NAVIER-STOKES COMPUTER CODE, VERSION 2.0. VOLUME 2: USER'S GUIDE

Charles E. Towne, John R. Schwab, and Trong T. Bui Oct. 1993 134 p

(RTOP 505-62-52)

(NASA-TM-106338-Vol-2; E-8107; NAS 1.15:106338-Vol-2) Avail: CASI HC A07/MF A02

A computer code called Proteus 2D was developed to solve the two-dimensional planar or axisymmetric, Reynolds-averaged, unsteady compressible Navier-Stokes equations in strong conservation law form. The objective in this effort was to develop a code for aerospace propulsion applications that is easy to use and easy to modify. Code readability, modularity, and documentation were emphasized. The governing equations are solved in generalized nonorthogonal body-fitted coordinates, by marching in time using a fully-coupled ADI solution procedure. The boundary conditions are treated implicitly. All terms, including the diffusion terms, are linearized using second-order Taylor series expansions. Turbulence is modeled using either an algebraic or two-equation eddy viscosity model. The thin-layer or Euler equations may also be solved. The energy equation may be eliminated by the assumption of constant total enthalpy. Explicit and implicit artificial viscosity may be used. Several time step options are available for convergence acceleration. The documentation is divided into three volumes. This is the User's Guide, and describes the program's features, the input and output, the procedure for setting up initial conditions, the computer resource requirements, the diagnostic messages that may be generated, the job control language used to run the program, and several test cases. ON THE INTERACTION BETWEEN THE SHOCK WAVE ATTACHED TO A WEDGE AND FREESTREAM DISTURBANCES Final Report

Peter W. Duck (Manchester Univ., England.), D. Glenn Lasseigne (Old Dominion Univ., Norfolk, VA.), and M. Y. Hussaini Washington Aug. 1993 48 p Submitted for publication

(Contracts NAS1-19480; NAS1-18605; RTOP 505-90-52-01)

(NASA-CR-191528; NAS 1.26:191528; ICASE-93-61) Avail: CASI HC A03/MF A01

A study of the interaction of small amplitude, unsteady, freestream disturbances with a shock wave induced by a wedge in supersonic flow is presented. These disturbances may be acoustic waves, vorticity waves, or entropy waves (or indeed a combination of all three). Their interactions then generate behind the shock disturbances of all three classes, an aspect that is investigated in some detail, our motivation being to investigate possible mechanisms for boundary-layer receptivity, caused through the amplification and modification of freestream turbulence through the shock-body coupling. Also, the possibility of enhanced mixing owing to additional vorticity produced by the shock-body coupling is investigated. Author (revised)

BOUNDARY LAYER FLOW OF AIR OVER WATER ON A FLAT PLATE Final Report

John Nelson (Air Force Systems Command, Wright-Patterson AFB, OH.), Amy E. Alving (Minnesota Univ., Minneapolis.), and Daniel D. Joseph (Minnesota Univ., Minneapolis.) Washington Aug. 1993 16 p Submitted for publication Sponsored in part by NSF, DOE, Dept. of the Army, Dept. of the Air Force, and Minnesota Univ.

(Contract NAS1-19480; RTOP 505-90-52-01)

(NASA-CR-191517; NAS 1.26:191517; ICASE-93-57) Avail: CASI HC A03/MF A01

A non-similar boundary layer theory for air blowing over a water layer on a flat plate is formulated and studied as a two-fluid problem in which the position of the interface is unknown. The problem is considered at large Reynolds number (based on x), away from the leading edge. A simple non-similar analytic solution of the problem is derived for which the interface height is proportional to x(sub 1/4) and the water and air flow satisfy the Blasius boundary layer equations, with a linear profile in the water and a Blasius profile in the air. Numerical studies of the initial value problem suggests that this asymptotic, non-similar air-water boundary layer solution is a global attractor for all initial conditions. Author (revised)

SURFACE AND INTERNAL SIGNATURES OF ORGANIZED VORTEX MOTIONS IN STRATIFIED FLUID

Y. T. Fung and S. W. Chang 15 Jul. 1993 50 p

(AD-A267015; NRL/MR/7225-93-7346) Avail: CASI HC A03/MF A01

Internal vortex patterns and the corresponding free surface signatures generated by a submerged sphere moving in a stratified fluid are numerically simulated by a three-dimensional time-dependent computer model. The flow is assumed to be incompressible and hydrostatic, and the Boussinesq approximation is applied. The turbulent mixing is modeled using the Smagorinsky formula for horizontal fluxes and a Richardson number closure for vertical fluxes. The numerical techniques include a second-order finite difference scheme with a staggered and stretched grid system. To efficiently handle the slow baroclinic and the fast barotropic modes in the flow, a split-explicit method is used to separately integrate the two modes in time. This method allows us to economically simulate the time history of the slowly evolving vortices. Preliminary results for the velocity field, the flow pattern, the density distribution, and the induced surface signature are presented. They consistently reveal the existence of coherent structures in the stratified flow field. A mechanism based on the interaction of the wake vorticity and the buoyancy induced oscillation is proposed for the generation and growth of the horizontal vortices in stratified fluids. This mechanism explains why the horizontal vortices appear long after the initial disturbances generated by a submerged moving body have dissipated, and why these vortices exist only in stratified fluids but not in homogenous media. In a forthcoming paper, we will examine how the density distribution, the depth of the moving object, and the depth of the channel floor affect the organized vortex structures and the corresponding surface signatures. NUMERICAL INVESTIGATIONS IN THREE-DIMENSIONAL INTERNAL FLOWS Semiannual Status Report, 1 Jul. - 31 Dec. 1993

William C. Rose 1993 26 p

(Contract NCC2-507)

(NASA-CR-194594; NAS 1.26:194594) Avail: CASI HC A03/MF A01

In the present reporting period, the 3D version of the OVERFLOW code was used to solve the flow within the internal portion of the supersonic inlet. The internal portion of this inlet is bounded by an inflow plane containing the leading edge of the sidewalls, the sidewalls, the ramp and cowl surfaces and an outflow plane just downstream of the minimum geometric area of the inlet. Boundary layer bleed was used in the two-dimensional calculations discussed in the previous progress report and that same bleed was applied in the present study. For reference, this bleed corresponds to locations designated as R2 and R3 in the Mach 5 inlet model test. Using the GRIDGEN code, a three dimensional grid was generated that accounted for the viscous effects expected to occur on the sidewall, as well as those known to occur on the ramp and cowl surfaces. The internal flow grid size was 141 streamwise by 101 cross stream by 71 in the lateral direction between sidewalls. Since the flow entering the inlet was not symmetrical, the inlet was solved from sidewall to sidewall (without using a symmetry plane). In addition to the short sidewalls proposed in the Langley geometry database, a set of shorter sidewalls was also investigated in the present study and was shown to have beneficial effects with respect to the flow distortion exiting the supersonic inlet. In addition to these calculations, additional 3D solutions using the OVERFLOW code were obtained for the flow downstream of the throat of the supersonic inlet, including a terminal shock wave system produced by a backpressured subsonic diffuser. INCORPORATION OF BOUNDARY LAYER HEATING PREDICTIVE METHODOLOGY INTO NSWCDD AEROPREDICTION CODE

Roy M. McInville and Frank G. Moore Feb. 1993 67 p

(AD-A267000; NSWCDD/TR-93/29) Avail: CASI HC A04/MF A01

Methods have been incorporated into the Naval Surface Warfare Center, Dahlgren Division aeroprediction code to permit the computation of heat transfer rates and recovery temperatures as part of the high Mach number solution. A mass balance technique has been included to determine the correct boundary layer edge entropy to use along the surface of blunt bodies. Refinements were also made to the pressure prediction routines to remove discontinuities and improve overall results. Comparisons of results from the new methods with those from more advanced engineering codes, with other techniques of similar technical level of detail, and with experimental data show good agreement. These new capabilities make possible the rapid computation of three-dimensional heat transfer information for a wide range of geometric configurations and flight conditions. DTIC

AN EXPERIMENTAL STUDY OF ASTOVL RELATED JET FLOWS TO PRODUCE CFD CODE VALIDATION DATA. PHASE 3: RESULTS OF EXPERIMENTS Final Report

P. Behrouzi and J. J. McGuirk Oct. 1992 60 p

(TT-9203; ISBN-0-904947-38-6; ETN-93-94492) Copyright Avail: CASI HC A04/MF A01

A study aimed at the provision of experimental data for mean velocities and associated turbulence quantities in flow fields related to the ground effect phase of Advanced Short Takeoff and Vertical Landing (ASTOVL) aircraft operation is reported. These data are intended to serve as a benchmark validation data set for RANS based Computational Fluid Dynamics (CFD) codes which might in the future be used in design studies of ASTOVL aircraft. To aid the specification of boundary conditions in related CFD calculations, and to allow the isolation of several physical phenomena believed to be important in ground effect flows (in particular fountain formation), three idealized jet flow configurations were selected for study: (1) lateral pair (twin jets with line of centers perpendicular to crossflow direction) to study effect of velocity ratio (jet velocity/crossflow velocity), jet impingement height, jet splay angle, and jet spacing; (2) longitudinal pair (twin jets with line of centers aligned with crossflow direction) to study effect of velocity ratio and jet imbalance; (3) and three poster (a combination of lateral and longitudinal pair) to study effect of rear jets splay angle and jet imbalance. Low speed incompressible flows were concentrated upon. The use of laser Doppler velocimetry was selected as the measurement technique to be used, and optical access and seeding problems could be alleviated considerably by the use of a water flow rather than an air flow. Accordingly a small scale water tunnel was selected as the test facility to be used to gather the data. ESA

THEORETICAL STUDY OF LAMINAR FILM CONDENSATION ON HORIZONTAL ELLIPITICAL TUBES UNDER CONDITIONS OF FREE AND FORCED CONVECTION M.S. Thesis
Vance H. Adams Mar. 1993 124 p
(AD-A267161) Avail: CASI HC A06/MF A02

Analytical studies have been made of laminar film condensation on a horizontal elliptical cylinder in a pure saturated vapor under conditions of free and forced convection. Estimation of interfacial shear stress was made in two ways: the first involving an asymptotic value of the shear stress under conditions of infinite condensation rate and the second based on simultaneously solving the two-phase vapor boundary layer and condensate equations. The latter approach enables the determination of the vapor boundary layer separation point. For the assumption of asymptotic shear stress, effects of surface tension and pressure gradient in the condensate film have been included. At the extremes of eccentricity, corresponding to a circular tube and a vertical plate, the results are compared with theoretical and experimental work of others. Improvement in the condensation heat transfer coefficient was found for elliptical tubes under both free and forced convection conditions when compared to circular tubes of the same surface area. In the latter case, this improvement was due mainly to the reduced drag of the elliptical tube providing a higher vapor velocity for the same pressure drop as that across a circular tube. DTIC

PARAMETRIC RESONANT TRIAD INTERACTIONS IN A FREE SHEAR LAYER
R. Mallier (McGill Univ., Montreal, Quebec.) and S. A. Maslowe Oct. 1993 23 p
(RTOP 505-90-5K)
(NASA-TM-106365; ICOMP-93-35; E-8166; NAS 1.15:106365) Avail: CASI HC A03/MF A01

We investigate the weakly nonlinear evolution of a triad of nearly-neutral modes superimposed on a mixing layer with velocity profile u bar equals Um + tanh y. The perturbation consists of a plane wave and a pair of oblique waves each inclined at approximately 60 degrees to the mean flow direction. Because the evolution occurs on a relatively fast time scale, the critical layer dynamics dominate the process and the amplitude evolution of the oblique waves is governed by an integro-differential equation. The long-time solution of this equation predicts very rapid (exponential of an exponential) amplification and we discuss the pertinence of this result to vortex pairing phenomena in mixing layers. EXPERIMENTAL INVESTIGATIONS INTO THE DEFLAGRATION TO DETONATION TRANSITION AT TNO/PML Final Report [HET EXPERIMENTELE ONDERZOEK NAAR DE DEFLAGRATIE NAAR DETONATIE OVERGANG OP PML/TNO]
H. J. Verbeek, R. Oostdam, and E. G. deJong Jan. 1993 31 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A266753; PML-1992-77; TDCK-92-2743) Avail: CASI HC A03

This report presents an overview of the experimental research that has been performed at TNO-PML from 1988 to 1991 on the subject of the transition from a deflagration to a detonation (DDT) in solid explosives. A full description is given of the set-up used for the experiments, of the development in time of the set-up, and of the rationale for the applied changes. Among the experimental results that are presented, the influence on the DDT process is shown of variations in parameters such as the tube geometry, the explosive density, the particle size, and the igniter strength. The results obtained at a relatively low wall thickness of the test-tube are particularly notable. DTIC

NUMERICAL SIMULATION OF THREE-DIMENSIONAL SELF-GRAVITATING FLOW
John V. Shebalin Aug. 1993 14 p Submitted for publication
(RTOP 505-90-52-01)
(NASA-TM-109021; ICASE-93-60; NAS 1.15:109021) Avail: CASI HC A03/MF A01

The three-dimensional flow of a self-gravitating fluid is numerically simulated using a Fourier pseudospectral method with a logarithmic variable formulation. Two cases with zero total angular momentum are studied in detail, a 323 simulation (Run B). Other than the grid size, the primary difference between the two cases are that Run A modeled atomic hydrogen and had considerably more compressible motion initially than Run B, which modeled molecular hydrogen. The numerical results indicate that gravitational collapse can proceed in a variety of ways. In the Run A, collapse led to an elongated tube-like structure, while in the Run B, collapse led to a flatter, disklike structure. Author (revised)

MECHANISM OF INTERMITTENT ATOMIZATION Final Report
S. P. Lin Jun. 1993 94 p
(Contract DAAL03-89-K-0179)
(AD-A266625; ARO-26797.10-EG) Avail: CASI HC A05/MF A01

A theory is developed for the purpose of enhancing the efficiency of internal combustion engines, and to reduce the air pollution caused by inefficient combustion. The theoretical results show that the droplet formation from the leading edge of the liquid fuel jet is caused by the Taylor-Lamb instability during the deceleration phase of the intermittent spray. The mechanism of droplet formation from the rest of the liquid-gas interface is caused by the interfacial stress fluctuation. The deceleration of the liquid jet tends to reduce the droplet diameter at the same pressure. However, finer sprays can be produced with a more sudden reduction in the nozzle inlet pressure after its peak during the injection period. An increase in the compressibility of the liquid jet is shown to promote the generation of smaller droplets, although at a slower rate. The compressibility of the ambient gas, as well as the surface tension, tends to promote absolute instability. The precise physical meaning remains unclear. The absolute instability can be reduced to convective instability by reducing the surface tension and/or increasing the compressibility of the jet fluid. The convective instability is responsible for the formation of sprays. DTIC

INVESTIGATION OF RADIATIVE INTERACTION IN LAMINAR FLOWS USING MONTE CARLO SIMULATION
Jiwen Liu and S. N. Tiwari Jun. 1993 33 p
(Grant NAG1-363)
(NASA-CR-194604; NAS 1.26:194604; ODU/ICAM-93-101) Avail: CASI HC A03/MF A01

The Monte Carlo method (MCM) is employed to study the radiative interactions in fully developed laminar flow between two parallel plates. Taking advantage of the characteristics of easy mathematical treatment of the MCM, a general numerical procedure is developed for nongray radiative interaction. The nongray model is based on the statistical narrow band model with an exponential-tailed inverse intensity distribution. To validate the Monte Carlo simulation for nongray radiation problems, the results of radiative dissipation from the MCM are compared with two available solutions for a given temperature profile between two plates. After this validation, the MCM is employed to solve the present physical problem and results for the bulk temperature are compared with available solutions. In general, good agreement is noted and reasons for some discrepancies in certain ranges of parameters are explained. Author

INVISCID INSTABILITY OF STREAMWISE CORNER FLOW
S. Balachandar (Illinois Univ., Urbana.) and M. R. Malik (High Technology Corp., Hampton, VA.) Washington Aug. 1993 25 p Submitted for publication
(Contracts NAS1-19480; NAS1-19299)
(NASA-CR-191514; ICASE-93-54; NAS 1.26:191514) Avail: CASI HC A03/MF A01

Linear stability of the incompressible flow along a stream wise corner is studied by solving the two-dimensional eigenvalue problem governed by partial differential equations. It is found that this fully three-dimensional flow is subject to inviscid instability due to the inflectional nature of the stream wise velocity profile. The higher growth rates for the inviscid instability mode, which is symmetric about the corner bisector, as compared to the viscous Tollmien-Schlichting instability operative away from the corner is

consistent with the experimental findings that the corner flow transitions to turbulence earlier than the two-dimensional Blasius flow away from the corner. Author

USAF PHYSIOLOGICAL STUDIES OF PERSONAL MICROCLIMATE COOLING: A REVIEW Final Report, Sep. 1980 - Dec. 1992
Stefan H. Constable May 1993 69 p
(AD-A267203; AL-TR-1993-0030) Avail: CASI HC A04/MF A01

The U.S. Air Force has accomplished a number of research studies which evaluated the efficacy of selected personal cooling approaches for alleviating heat stress in personnel wearing certain protective clothing. Most of this work involved laboratory, as opposed to field, studies and incorporated human subjects performing work in either warm or hot environments. Both air and liquid microclimate cooling systems were evaluated. The general findings include the following: (1) personal microclimate cooling systems (both air and liquid) were shown to remove significant quantities of body heat; (2) in general, commercially available systems were inferior to in-house prototype units; (3) backpack (ambulatory) systems usage would likely have a limited user audience for a number of reasons; (4) some near-term, partial solutions to the problem may be at hand for selected deployments; and (5) microclimate cooling technologies on the horizon will likely not provide an optimum solution for most ground crew applications. The USAF Armstrong Laboratory has limited plans for further research in this area. DTIC

RECEPTIVITY OF BOUNDARY LAYERS TO CONVECTED GUSTS Final Report, 1 Apr. 1990 - 31 Mar. 1993
D. E. Parekh 31 Mar. 1993 43 p
(Contract F49620-90-C-0031)
(AD-A267206; AFOSR-93-0458TR) Avail: CASI HC A03/MF A01

The primary objective of this study is to determine experimentally the receptivity of a laminar boundary layer to convected gusts. Receptivity is the process by which external disturbances transfer energy to instabilities in the boundary layer. The term convected gust refers to a transient or periodic vortical disturbance convected by the freestream. The experimental approach consisted of hot-wire studies of the boundary layer response to vortical disturbances produced by an array of oscillating ribbons. The boundary layer is remarkably insensitive to large-scale vortical perturbations. No significant Tollmien-Schlichting waves were observed. The vortical disturbances are rapidly damped in the boundary layer and cause only weak oscillations that are primarily of the same frequency and wavelength as the external disturbance. DTIC

(RTOP 505-62-52)
(NASA-TM-106341; E-8110; NAS 1.15:106341) Avail: CASI HC A13/MF A03

A computer code called Proteus 3D was developed to solve the three-dimensional, Reynolds-averaged, unsteady compressible Navier-Stokes equations in strong conservation law form. The objective in this effort was to develop a code for aerospace propulsion applications that is easy to use and easy to modify. Code readability, modularity, and documentation were emphasized. The governing equations are solved in generalized nonorthogonal body fitted coordinates, by marching in time using a fully-coupled ADI solution procedure. The boundary conditions are treated implicitly. All terms, including the diffusion terms, are linearized using second-order Taylor series expansions. Turbulence is modeled using either an algebraic or two-equation eddy viscosity model. The thin-layer or Euler equations may also be solved. The energy equation may be eliminated by the assumption of constant total enthalpy. Explicit and implicit artificial viscosity may be used. Several time step options are available for convergence acceleration. The documentation is divided into three volumes. The Programmer's Reference contains detailed information useful when modifying the program. The program structure, the Fortran variables stored in common blocks, and the details of each subprogram are described. Author (revised)

TURBULENCE AND TRANSITION MODELING FOR HIGH-SPEED FLOWS Final Report, 15 Sep. 1989 - 14 Mar. 1993
David C. Wilcox 15 Apr. 1993 16 p
(Contract DAAL03-92-G-0188)
(AD-A266748; ARO-26863.8-EG-S) Avail: CASI HC A03/MF A01

This report summarizes research conducted during the past three and a half years aimed at developing and testing a turbulence/transition model applicable to high-speed turbulent flows. The first two years of the project focused on fully turbulent flows, while emphasis shifted to boundary-layer development in the transition region during the final year and a half. This report includes a brief summary of research accomplished during the first three years and cites publications that describe research results in greater detail. The main body of this report summarizes research conducted during the final six months of the period of performance. The primary results of the last six months of the project are elimination of the k-omega model's sensitivity to the freestream value of omega and development of a method for triggering transition at a specified location, independent of the freestream turbulence level. GEOMETRICAL VAPOR BLOCKER FOR PARALLEL CONDENSATION TUBES REQUIRING COOLING Patent Application
Eugene Ungar, inventor (to NASA), John Cornwell, inventor (to NASA), and William Harwell, inventor (to NASA) 3 Sep. 1993 20 p
(NASA-Case-MSC-22090-1; NAS 1.71:MSC-22090-1;
US-Patent-Appl-SN-115832) Avail: CASI HC A03/MF A01

An apparatus and method is disclosed for regulating flow of working fluid through parallel condensation tubes requiring subcooling. The apparatus provides an elongated restriction element extending into the outlet of the respective condensation tubes to the approximate point of onset of subcooling. The elongated restriction element is braced externally to the condensation tube with a support that is used for positioning and maintaining the elongated restriction element in the correct position. The elongated restriction element has a pentagonal cross-section and is slightly undersized with respect to the working fluid passageways through the condensation tubes. The restriction member significantly restricts flow of partially vaporized

working fluid but does not significantly affect the flow of fully liquid working fluid. NASA

BROKEN SYMMETRY IN IDEAL MAGNETOHYDRODYNAMIC TURBULENCE
John V. Shebalin Washington Aug. 1993 17 p Submitted for publication
(RTOP 505-90-52-01)
(NASA-TM-109017; ICASE-93-49; NAS 1.15:109017) Avail: CASI HC A03/MF A01

A numerical study of the long-time evolution of a number of cases of inviscid, isotropic, incompressible, three-dimensional fluid, and magneto-fluid turbulence has been completed. The results confirm that ideal magnetohydrodynamic turbulence is non-ergodic if there is no external magnetic field present. This is due essentially to a canonical symmetry being broken in an arbitrary dynamical representation. The broken symmetry manifests itself as a coherent structure, i.e., a non-zero time-averaged part of the turbulent magnetic field. The coherent structure is observed, in one case, to contain about eighteen percent of the total energy. Author (revised)

GAM-HEAT: A COMPUTER CODE TO COMPUTE HEAT TRANSFER IN COMPLEX ENCLOSURES
R. E. Cooper and J. R. Taylor Dec. 1992 100 p
(Contract DE-AC09-89SR-18035)
(DE93-014724; WSRC-TR-91-372-Rev-2) Avail: CASI HC A05/MF A02

This report discusses the GAM-HEAT code which was developed for heat transfer analyses associated with postulated Double Ended Guillotine Break Loss Of Coolant Accidents (DEGB LOCA) resulting in a drained reactor vessel. In these analyses the gamma radiation resulting from fission product decay constitutes the primary source of energy as a function of time. This energy is deposited into the various reactor components and is re-radiated as thermal energy. The code accounts for all radiant heat exchanges within and leaving the reactor enclosure. The SRS reactors constitute complex radiant exchange enclosures since there are many assemblies of various types within the primary enclosure and most of the assemblies themselves constitute enclosures. GAM-HEAT accounts for this complexity by processing externally generated view factors and connectivity matrices as discussed below, and also accounts for convective, conductive, and advective heat exchanges. The code is structured such that it is applicable for many situations involving heat exchange between surfaces within a radiatively passive medium. DOE

EFFECTS OF ROTATION ON COOLANT PASSAGE HEAT TRANSFER. VOLUME 2: COOLANT PASSAGES WITH TRIPS NORMAL AND SKEWED TO THE FLOW Final Report
B. V. Johnson, J. H. Wagner, and G. D. Steuber Washington Oct. 1993 123 p
(Contract NAS3-23691; RTOP 505-62-61)
(NASA-CR-4396-Vol-2; E-6470-1; NAS 1.26:4396-Vol-2) Avail: CASI HC A06/MF A02

An experimental program was conducted to investigate heat transfer and pressure loss characteristics of rotating multipass passages, for configurations and dimensions typical of modern turbine blades. This experimental program is one part of the NASA Hot Section Technology (HOST) Initiative, which has as its overall objective the development and verification of improved analysis methods that will form the basis for a design system that will produce turbine components with improved durability. The objective of this program was the generation of a data base of heat transfer and pressure loss data required to develop heat transfer correlations and to assess computational fluid dynamic techniques for rotating coolant passages. The experimental work was broken down into two phases. Phase 1 consists of experiments conducted in a smooth wall large scale heat transfer model. A detailed discussion of these results was presented in volume 1 of a NASA Report. In Phase 2 the large scale model was modified to investigate the effects of skewed and normal passage turbulators. The results of Phase 2 along with comparison to Phase 1 is the subject of this Volume 2 NASA Report. Author (revised)

VENTILATED OSCILLATORY BOUNDARY LAYERS
Daniel C. Conley and Douglas L. Inman Feb. 1993 80 p
(Contract N00014-89-J-1060)
(AD-A266226) Avail: CASI HC A05/MF A01

A combination of field and laboratory experiments are made in order to expand our knowledge of naturally occurring oscillatory boundary layers. Chapter 1 describes field observations of the development of wave driven boundary layers at the fluid sediment interface. Under the crest of the wave, this development can be idealized as an identifiable sequence of three parts. The latter parts of this development are never observed to occur under the trough of the wave despite similarities in wave orbital velocity and acceleration. It is proposed that wave induced boundary ventilation, the oscillatory flow through the surface of a permeable bed, may be responsible for this apparent developmental asymmetry. In chapter 2, a laboratory study is presented of ventilated oscillatory boundary layers. These are boundary layers arising from a flow which oscillates parallel to a permeable bed which is subject to oscillating percolation of the same frequency as the bed parallel flow. Measurements of boundary layer velocities, bed stress and turbulent flow properties are presented. It is observed that suction (flow into the bed) enhances the near bed velocities and bed stress while injection (flow out of the bed) leads to a reduction in these quantities. As the ventilated oscillatory boundary layer experiences both these phenomena in one full cycle, the result is a net stress and a net boundary layer velocity in an otherwise symmetric flow. While production of turbulence attributable to injection is enhanced, the finite time required for this to occur leads to greater vertically averaged turbulence in the suction half cycle. Turbulence generated in the suction half cycle is maintained in a compact layer much closer to the bed. These effects appear to hold for Re ranging from 10(exp 5) to 10(exp 6) and for oscillations other than sinusoidal. DTIC

IMPLEMENTATION OF AN ANISOTROPIC TURBULENCE MODEL IN THE COMMIX-1C/ATM COMPUTER CODE
M. Bottoni and F. C. Chang 1993 19 p Presented at the Pressure Vessels and Piping Conference, Denver, CO, 25-29 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-015541; ANL/MCT/CP-78185; CONF-930702-38) Avail: CASI HC A03/MF A01

The computer code COMMIX-1C/ATM, which describes single-phase, three-dimensional transient thermofluid dynamic problems, provided the framework for the extension of the standard kappa-epsilon turbulence model to a six-equation model with additional transport equations for the turbulence heat fluxes and the variance of temperature fluctuations. The new model which allows simulation of anisotropic turbulence in stratified shear flows is referred to as the Anisotropic Turbulence Model (ATM). The ATM has been verified with numerical computations of stable and unstable stratified shear flow between parallel plates. DOE

SEARCH FOR CHAOS IN FREE SHEAR FLOWS Final Technical Report, 1 May 1990 - 30 Sep. 1992
Ho Chih-Ming, Patrick Huerre, and Larry G. Redekopp 1 Sep. 1992 7 p
(Grant AF-AFOSR-0299-90)
(AD-A266245; AFOSR-93-0453TR) Avail: CASI HC A02/MF A01

Theoretical studies on the temporal and spatial structure in blunt-body wakes have revealed the necessary conditions under which global, self-sustained oscillations appear and have provided firm criteria for specifying the frequency of these oscillations. The theory has also been employed to describe the preferred mode in jets. The two-dimensional structure of these modes provides a firm basis for describing the spatial structure of the vortex pattern observed in wakes. In addition, a theoretical description of the appearance of the spatial chaos in wake-shear layers, and its representation in terms of a one-dimensional map, has been provided. An experimental facility and necessary instrumentation have been assembled and experiments are in progress on spatial chaos in wake-shear layers. Experimental results have revealed a parameter domain where a temporal

vacillation occurs between the Karman mode and the shear layer mode. Interesting results with possible application to thrust-vectoring of base flows have also been identified. DTIC

FLUID FLOW AND HEAT CONVECTION STUDIES FOR ACTIVELY COOLED AIRFRAMES Report, Apr. - Nov. 1993
A. F. Mills 1993 14 p
(Contract NCC2-374)
(NASA-CR-194624; NAS 1.26:194624) Avail: CASI HC A03/MF A01

This report details progress made on the jet impingement - liquid crystal - digital imaging experiment. With the design phase complete, the experiment is currently in the construction phase. In order to reach this phase two design related issues were resolved. The first issue was to determine NASP leading edge active cooling design parameters. Meetings were arranged with personnel at SAIC International, Torrance, CA in order to obtain recent publications that characterized expected leading edge heat fluxes as well as other details of NASP operating conditions. The information in these publications was used to estimate minimum and maximum jet Reynolds numbers needed to accomplish the required leading edge cooling, and to determine the parameters of the experiment. The details of this analysis are shown in Appendix A. One of the concerns for the NASP design is that of thermal stress due to large surface temperature gradients. Using a series of circular jets to cool the leading edge will cause a non-uniform temperature distribution and potentially large thermal stresses. Therefore it was decided to explore the feasibility of using a slot jet to cool the leading edge. The literature contains many investigations into circular jet heat transfer but few investigations of slot jet heat transfer. The first experiments will be done on circular jets impinging on a flat plate and results compared to previously published data to establish the accuracy of the method. Subsequent experiments will be slot jets impinging on full scale models of the NASP leading edge. Table 1 shows the range of parameters to be explored. Next a preliminary design of the experiment was done. Previous papers which used a similar experimental technique were studied and elements of those experiments adapted to the jet impingement study. Trade-off studies were conducted to determine which design was the least expensive, easy to construct, and easy to use. Once the final design was settled, vendors were contacted to verify that equipment could be obtained to meet our specifications. Much of the equipment required to complete the construction of the experiment has been ordered or received. The material status list is shown in Appendix B. Author

(Grant AF-AFOSR-0117-91)
(AD-A266421) Avail: CASI HC A06/MF A02

Experimental investigations and analyses have been performed to study the behavior of granular materials with respect to their nonassociated flow and instability under certain loading conditions. All experiments have been performed in triaxial compression and extension at high as well as at low confining pressures. Major topics that were studied include: strain localization in triaxial extension tests; drained and undrained stress-strain and strength behavior from low to high pressures in triaxial extension and compression; instability of granular materials at high pressures in triaxial compression and extension; the determination of Skempton's pore pressure parameter B at high pressures; strain rate effects of granular materials at high pressures in drained and undrained conditions; examination of the effective stress principle at high pressures; particle breakage at high pressures; behavior of sand in one-dimensional compression tests at very high pressures; determination of values of K(sub o), the coefficient of earth pressure at rest, at high pressures; evaluation of the elastic modulus and Poisson's ratio at high pressure levels; correlations of high pressure soil behavior with stress-dilatancy, critical state, and input energy; static instability and liquefaction of loose fine sandy slopes; stability of granular materials in post peak softening regime; instability of dilating sand; and creep effects on static and cyclic instability of granular soils. STABILITY OF FLOWS IN FLUIDIZED BEDS
Apr. 1993 76 p
(Contract DE-AC21-89MC-26302)
(DE93-000245; DOE/MC-26302/3269) Avail: CASI HC A05/MF A01

We study the linearized stability of the state of uniform fluidization, within the context of the theory of mixtures. The mixture is assumed to be made up of a classical linearly viscous fluid mixed with solid particles. In marked departure from most of the previous studies, we model the solid as a granular material and assume a constitutive relation that stems from classical motions in continuum mechanics. The linearized stability analysis of the state of uniform fluidization, in general, leads to an eighth order equation for the characteristic whose root implies instability, when positive. We find that the characteristic equation can be factored and one of the factors is precisely the equation that governs the stability when we use a simplified analysis akin to that of the earlier study of Anderson and Jackson. CYCLE PERFORMANCE TESTING OF NONAZEOTROPIC MIXTURES OF HFC-142A/HCFC-124 AND HFC-32/HCFC-124 WITH ENHANCED SURFACE HEAT EXCHANGERS
E. A. Vineyard, J. C. Conklin, and A. J. Brown 1993 20 p Presented at the 1993 American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) Summer Meeting, Denver, CO, 26-30 Jan. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015215; CONF-930675-4) Avail: CASI HC A03/MF A01

In an effort to improve the efficiency of residential heat pumps using alternative refrigerants, two nonazeotropic refrigerant mixtures (NARM's) were tested over a range of heat exchanger capacities to determine their

cooling mode performance at US Department of Energy (DOE) heat pump rating conditions of 82 F (27.8 C). The two mixtures, 30% HFC-32/70% HCFC-124 and 75% HFC-143a/25% HCFC-124, were selected on the basis of a previous study that screened refrigerant pairs using such factors as boiling point, stability, ozone depletion potential (ODP), and coefficient of performance (COP) to determine suitable candidates for residential heat pump performance. Three refrigerant-side heat transfer enhancements were tested to determine improvements to overall system performance. Comparisons were made on the basis of the COP as a function of capacity. The results for one of the heat exchanger combinations, a segmented evaporator and finned condenser, were quite promising. Improvements in COP, relative to that for HCFC-22, were from 9 to 17% for the 30% HFC-32/70% HCFC-124 mixture and from 5 to 9% for the 75% HFC-143a/25% HCFC-124 NARM. Another combination, a smooth tube evaporator with a perforated foil insert and finned condenser, had similar gains at low capacities but experienced decreased performance at the higher capacities. The final combination, a smooth tube evaporator with a perforated foil insert and smooth tube condenser with a bent tab insert resulted in poor performance. DOE

NUMERICAL STUDY OF COMPRESSIBLE BOUNDARY-LEVEL TRANSITION BETWEEN TWO CONCENTRIC CYLINDERS Final Report, 15 Apr. 1990 - 31 Oct. 1993

Chuen-Yen Chow 31 Oct. 1993 2 p

(Contract NCC3-168)

(NASA-CR-194622; NAS 1.26:194622) Avail: CASI HC A01/MF A01

The period of support of this Cooperative Agreement was from April 15, 1990 to October 31, 1992, with a no-cost extension to October 31, 1993 to complete some unfinished tasks. Within this period, research associate Dr. Kai-Hsiung Kao has made tremendous contributions to this project and has produced an impressive amount of publications. At the early stage of the research, he spent some time on the extension of his doctoral thesis in a subject closely related to the present project. His major research effort was devoted to the investigation of stability of a viscous flow between two differentially rotating cylinders, with an emphasis on the effects of compressibility and heat transfer. Actually, the research topics were not restricted to those described by the title of this Agreement, as reflected in some of the more recent publications. Derived from text

COMPUTATION OF CONFINED COFLOW JETS WITH THREE TURBULENCE MODELS

J. Zhu and T. H. Shih Jul. 1993 13 p Presented at the 24th AIAA Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA

(Contract NCC2-233; RTOP 505-90-5K)

(NASA-TM-106378; ICOMP-93-40; CMOTT-93-14; AIAA Paper 93-3120; E-8191; NAS 1.15:106378) Avail: CASI HC A03/MF A01

A numerical study of confined jets in a cylindrical duct is carried out to examine the performance of two recently proposed turbulence models: an RNG-based K-epsilon model and a realizable Reynolds stress algebraic equation model. The former is of the same form as the standard K-epsilon model but has different model coefficients. The latter uses an explicit quadratic stress-strain relationship to model the turbulent stresses and is capable of ensuring the positivity of each turbulent normal stress. The flow considered involves recirculation with unfixed separation and reattachment points and severe adverse pressure gradients, thereby providing a valuable test of the predictive capability of the models for complex flows. Calculations are performed with a finite-volume procedure. Numerical credibility of the solutions is ensured by using second-order accurate differencing schemes and sufficiently fine grids. Calculations with the standard K-epsilon model are also made for comparison. Detailed comparisons with experiments show that the realizable Reynolds stress algebraic equation model consistently works better than does the standard K-epsilon model in capturing the essential flow features, while the RNG-based K-epsilon model does not seem to give improvements over the standard K-epsilon model under the flow conditions considered. ADAPTIVE CARTESIAN GRID METHODS FOR REPRESENTING GEOMETRY IN INVISCID COMPRESSIBLE FLOW

R. B. Pember, J. B. Bell, W. Y. Crutchfield, M. L. Welcome, and P. Colella (California Univ., Berkeley.) 1993 11 p Presented at the 11th International Computational Fluid Dynamics Conference, 28th Thermophysics Conference and 23rd Fluid Dynamics, Plasma Dynamics and Laser Conference, Orlando, FL, 5-7 Jul. 1993

(Contracts W-7405-eng-48; DE-FG03-92ER-25140)

(DE93-016430; UCRL-JC-113851; CONF-930714-1) Avail: CASI HC A03/MF A01

In this paper, we describe a Cartesian grid algorithm for modeling time-dependent compressible flow in complex geometry. In this approach, the problem geometry is treated as an interface embedded in a regular Cartesian mesh. The discretization near the embedded boundary is based on a volume-of-fluid approach with a redistribution procedure to avoid time-step restrictions arising from small cells where the boundary intersects the mesh. The algorithm is coupled to an unsplit, second-order Godunov algorithm and is fully conservative maintaining conservation at the boundary. The Godunov/Cartesian grid integration scheme is coupled to a local adaptive mesh refinement algorithm that selectively refines regions of the computational grid to achieve a desired level of accuracy. Examples showing the results of the combined Cartesian grid/local refinement algorithm for both two- and three-dimensional flows are presented. DOE

THREE DIMENSIONAL HYDRODYNAMIC CALCULATIONS WITH ADAPTIVE MESH REFINEMENT OF THE EVOLUTION OF RAYLEIGH TAYLOR AND RICHTMYER MESHKOV INSTABILITIES IN CONVERGING GEOMETRY: MULTI-MODE PERTURBATIONS

R. I. Klein, J. Bell, R. Pember, and T. Kelleher Apr. 1993 16 p Presented at the 4th International Workshop on the Physics of Compressible Turbulent Mixing, Cambridge, (United Kingdom), 29 Mar. - 1 Apr. 1993

(Contract W-7405-eng-48)

(DE93-017155; UCRL-JC-114505; CONF-9303126-4) Avail: CASI HC A03/MF A01

The authors present results for high resolution hydrodynamic calculations of the growth and development of instabilities in shock driven imploding spherical geometries in both 2D and 3D. They solve the Eulerian equations of hydrodynamics with a high order Godunov approach using local adaptive mesh refinement to study the temporal and spatial development of the turbulent mixing layer resulting from both Richtmyer-Meshkov and Rayleigh-Taylor instabilities. The use of a high resolution Eulerian discretization with adaptive mesh refinement permits them to study the detailed three-dimensional growth of multi-mode perturbations far into the non-linear regime for converging geometries. They discuss convergence properties of the simulations by calculating global properties of the flow. They discuss the time evolution of the turbulent mixing layer and compare its development to a simple theory for a turbulent mix model in spherical geometry based on Plesset's equation. Their 3D calculations show that the constant found in the planar incompressible experiments of Read and Young's may not be universal for converging compressible flow. They show the 3D time trace of transitional onset to a mixing state using the temporal evolution of volume rendered imaging. Their preliminary results suggest that the turbulent mixing layer loses memory of its initial perturbations for classical Richtmyer-Meshkov and Rayleigh-Taylor instabilities in spherically imploding shells. They discuss the time evolution of mixed volume fraction and the role of vorticity in converging 3D flows in enhancing the growth of a turbulent mixing layer. DOE

THREE-DIMENSIONAL TURBULENT BOUNDARY LAYER Final Report, 25 Jan. 1991 - 24 Jul. 1992

Parviz Moin 6 Jan. 1993 120 p

(Grant AF-AFOSR-0174-91)

(AD-A266261; SU-TR-57; AFOSR-93-0459TR) Avail: CASI HC A06/MF A02

The near wall mechanics of 3D turbulent boundary layers were studied using direct numerical simulation. A fully developed turbulent channel flow was suddenly subjected to a transverse pressure gradient. An explanation for the reduction in the Reynolds stresses, observed in experiments, was provided in terms of the dynamics of near-wall streamwise vortices in

turbulent boundary layers. It was shown that the effect of three-dimensionality is to change the trajectory of fluid particles in the vicinity of these vortices, and how this change leads to reductions of turbulence stresses. The proposed mechanisms are consistent with numerous statistical data and correlations which are presented. DTIC

NONLINEAR PROBLEMS IN FLUID DYNAMICS AND INVERSE SCATTERING Annual Report, 1 Jan. 1992 - 31 May 1993
Mark J. Ablowitz, Gregory Beylkin, and Duane P. Sather 31 May 1993 16 p
(Contract N00014-91-J-4037)
(AD-A266234; Rept-153-4645) Avail: CASI HC A03/MF A01

The inverse scattering of a class of differential-difference equations and multidimensional operators has been constructed. Solutions of nonlinear wave equations arising in fluid dynamics and plasma physics were found and analyzed. Novel and fast computational algorithms were developed and in relevant nonlinear problems wavelet bases with controlled localization properties in the time-frequency domain have proven to be an effective tool. Landau type amplitude equations governing the small gap Taylor problem have been obtained and analyzed. Detailed project summaries and research activities are given in the attached document. A list of published papers, preprints, and invited lectures are included. DTIC

THE STRUCTURE OF TURBULENT BOUNDARY LAYERS AND SHOCK WAVE BOUNDARY LAYER INTERACTIONS Final Report, 15 Jun. 1989 - 14 Oct. 1992
Alexander J. Smits 13 Apr. 1993 23 p
(Grant AF-AFOSR-0420-89)
(AD-A266240; AFOSR-93-0451TR) Avail: CASI HC A03/MF A01

This report is the Final Technical Report for AFOSR Grant 89-0420, monitored by Dr James McMichael, for the period June 15, 1989 to October 14, 1992. Under this program, research was performed (1) to describe the structure of the large-scale motions in supersonic turbulent boundary layers, (2) to study the interaction of that turbulence with shock waves and strategies for controlling the interaction, (3) to differentiate between Mach and Reynolds number effects on turbulence structure in wall-bounded flows, and (4) to develop and implement new non-intrusive diagnostic techniques. The research is aimed at providing physical insight, and scaling information, for the development of turbulence models appropriate for supersonic shear layers. The primary experimental means used in these investigations were the Rayleigh scattering technique to study the instantaneous density field, the RELIEF line tagging method to study the instantaneous velocity field, and a dual hot-wire technique to obtain simultaneous velocity and density signals. STUDIES IN TURBULENCE AND TURBULENCE CONTROL Final Technical Report, 1 Jan. 1990 - 31 Dec. 1992
K. R. Sreenivasan 6 Jun. 1993 79 p
(Grant AF-AFOSR-0139-91)
(AD-A266318; AFOSR-93-0449TR) Avail: CASI HC A05/MF A01

A summary of the research performed under this grant is provided. It consists of work that bears on reacting flow research as well as basic turbulence studies. In the former category, the research involves differential diffusion, photobleaching, conditional scalar dissipation, helium jets, and the thickness-distribution of OH regions in diffusion flames. In the former category, the summary is limited to Kolmogorov's refined hypothesis, self-affine traces of turbulent signals, synthetic turbulence, wavelet decomposition of turbulence, and the intermittency exponent in the turbulence dissipation. Only briefly mentioned are other aspects such as the scaling of structure functions, the scaling of circulation, and the effect of filtering on Kolmogorov's 4/5 relation. DTIC

STABILITY ANALYSIS FOR THE FLOW OF GRANULAR MATERIALS DOWN AN INCLINED PLANE USING KINETIC MODEL
K. R. Rajagopal 1993 10 p
(Contract DE-AC22-91PC-90180)
(DE93-016852; DOE/PC-90180/T7) Avail: CASI HC A02/MF A01

In the previous report the linearized stability equations for the flow of granular materials down an inclined plane, modeled by the kinetic constitutive theory of Richman & Marciniec were derived. Here, we use the approximate solution of Richman & Marciniec as the base solution for the linearized stability analysis. The governing equations obtained are solved numerically to obtain the marginal stability curves which are presented in this report. DOE

NATURAL CONVECTION ABOVE A HORIZONTAL HEAT SOURCE M.S. Thesis
Adrian J. Jansen Mar. 1993 73 p
(AD-A267212) Avail: CASI HC A04/MF A01

An investigation of natural convection heat transfer from a flush mounted heater on a larger horizontal substrate in water has been conducted. The focus of the present investigation was on the buoyant flow above the heat source. Temperature measurements in the buoyant plume were made at various locations and heights, for a number of input powers using a traversing thermocouple probe. Simple signal processing was performed on the temperature measurements to attempt to investigate the reported meandering motions in the plume and the transition from laminar to turbulent buoyant flow. These measurements are interpreted based on flow visualizations. DTIC

Two fourth order accurate Osher schemes are presented which maintain higher order accuracy on nonuniform grids. They use either a conservative finite difference or finite volume discretization. Both methods are successfully used for direct numerical simulations of flat plate boundary layer instability at different Mach numbers. Results of growth rates of Tollmien-Schlichting

waves compare well with direct simulations of incompressible flow and for compressible flow with results obtained by solving the parabolic stability equations. Author

AN UPWIND MULTIGRID METHOD FOR SOLVING VISCOUS FLOWS ON UNSTRUCTURED TRIANGULAR MESHES M.S. Thesis
Daryl Lawrence Bonhaus (George Washington Univ., Hampton, VA.) 13 Aug. 1993 58 p
(NASA-TM-109343; NAS 1.15:109343) Avail: CASI HC A04/MF A01

A multigrid algorithm is combined with an upwind scheme for solving the two dimensional Reynolds averaged Navier-Stokes equations on triangular meshes resulting in an efficient, accurate code for solving complex flows around multiple bodies. The relaxation scheme uses a backward-Euler time difference and relaxes the resulting linear system using a red-black procedure. Roe's flux-splitting scheme is used to discretize convective and pressure terms, while a central difference is used for the diffusive terms. The multigrid scheme is demonstrated for several flows around single and multi-element airfoils, including inviscid, laminar, and turbulent flows. The results show an appreciable speed up of the scheme for inviscid and laminar flows, and dramatic increases in efficiency for turbulent cases, especially those on increasingly refined grids. NONEQUILIBRIUM RADIATION AND CHEMISTRY MODELS FOR AEROCAPTURE VEHICLE FLOWFIELDS Semiannual Progress Report, Jan. - Jun. 1993
Leland A. Carlson Sep. 1993 39 p
(Grant NAG1-1003)
(NASA-CR-194645; NAS 1.26:194645; TAMRF-6382-93-02) Avail: CASI HC A03/MF A01

The period from Jan. 1993 thru Aug. 1993 is covered. The primary tasks during this period were the development of a single and multi-vibrational temperature preferential vibration-dissociation coupling model, the development of a normal shock nonequilibrium radiation-gasdynamic coupling model based upon the blunt body model, and the comparison of results obtained with these models with experimental data. In addition, an extensive series of computations were conducted using the blunt body model to develop a set of reference results covering a wide range of vehicle sizes, altitudes, and entry velocities. THERMALLY-SUSTAINED STRUCTURE IN CONVECTIVELY UNSTABLE SYSTEMS
Robert J. Deissler Nov. 1993 17 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106375; ICOMP-93-39; E-8185; NAS 1.15:106375) Avail: CASI HC A03/MF A01

The complex Ginzburg-Landau equation with a thermal noise term is studied under conditions when the system is convectively unstable. Under these conditions, the noise is selectively and spatially amplified giving rise to a noise-sustained structure. Analytical results, applicable to a wide range of physical systems, are derived for the variance, and the coefficients and thermal noise term are determined for Taylor-Couette flow with an axial through-flow. Comparison is made to recent experiments. Author

INVESTIGATION OF HIGH-SPEED FREE SHEAR FLOWS USING IMPROVED PRESSURE-STRAIN CORRELATED REYNOLDS STRESS TURBULENCE MODEL Supplemental Progress Report for period ending Aug. 1991
S. N. Tiwari and B. Lakshmanan Nov. 1993 29 p
(Grant NAG1-423)
(NASA-CR-194661; NAS 1.26:194661) Avail: CASI HC A03/MF A01

A high-speed shear layer is studied using compressibility corrected Reynolds stress turbulence model which employs newly developed model for pressure-strain correlation. MacCormack explicit prediction-corrector method is used for solving the governing equations and the turbulence transport equations. The stiffness arising due to source terms in the turbulence equations is handled by a semi-implicit numerical technique. Results obtained using the new model show a sharper reduction in growth rate with increasing convective Mach number. Some improvements were also noted in the prediction of the normalized streamwise stress and Reynolds shear stress. The computed results are in good agreement with the experimental data. Author

ON SOLVING THE COMPRESSIBLE NAVIER-STOKES EQUATIONS FOR UNSTEADY FLOWS AT VERY LOW MACH NUMBERS
R. H. Pletcher and K.-H. Chen (Ohio Aerospace Inst., Brook Park.) Jul. 1993 13 p Presented at the 24th Fluid Dynamics Conference, orlando, FL, 6-9 Jul. 1993; sponsored by AIAA See also A93-45061
(RTOP 505-90-5K)
(NASA-TM-106380; ICOMP-93-42; AIAA Paper 93-3368; E-8193; NAS 1.15:106380) Avail: CASI HC A03/MF A01

The properties of a preconditioned, coupled, strongly implicit finite difference scheme for solving the compressible Navier-Stokes equations in primitive variables are investigated for two unsteady flows at low speeds, namely the impulsively started driven cavity and the startup of pipe flow. For the shear-driven cavity flow, the computational effort was observed to be nearly independent of Mach number, especially at the low end of the range considered. This Mach number independence was also observed for steady pipe flow calculations; however, rather different conclusions were drawn for the unsteady calculations. In the pressure-driven pipe startup problem, the compressibility of the fluid began to significantly influence the physics of the flow development at quite low Mach numbers. The present scheme was observed to produce the expected characteristics of completely incompressible flow when the Mach number was set at very low values. Good agreement with incompressible results available in the literature was observed. Author

STRUCTURE OF TURBULENCE IN THREE-DIMENSIONAL BOUNDARY LAYERS Final Technical Report
Chelakara S. Subramanian 1993 23 p
(Grant NAG1-1541)
(NASA-CR-194655; NAS 1.26:194655) Avail: CASI HC A03/MF A01

This report provides an overview of the three dimensional turbulent boundary layer concepts and of the currently available experimental information for their turbulence modeling. It is found that more reliable turbulence data, especially of the Reynolds stress transport terms, is needed to improve the existing modeling capabilities. An experiment is proposed to study the three dimensional boundary layer formed by a 'sink flow' in a fully developed two dimensional turbulent boundary layer. Also, the mean and turbulence field measurement procedure using a three component laser Doppler velocimeter is described. Author

STUDIES ON NONEQUILIBRIUM PHENOMENA IN SUPERSONIC CHEMICALLY REACTING FLOWS Progress Report for period ending 31 Aug. 1993
S. N. Tiwari and Rajnish Chandrasekhar Nov. 1993 139 p

(Grant NAG1-423)
(NASA-CR-194662; NAS 1.26:194662) Avail: CASI HC A07/MF A02

This study deals with a systematic investigation of nonequilibrium processes in supersonic combustion. The two-dimensional, elliptic Navier-Stokes equations are used to investigate supersonic flows with nonequilibrium chemistry and thermodynamics, coupled with radiation, for hydrogen-air systems. The explicit, unsplit MacCormack finite-difference scheme is used to advance the governing equations in time, until convergence is achieved. For a basic understanding of the flow physics, premixed flows undergoing finite rate chemical reactions are investigated. Results obtained for specific conditions indicate that the radiative interactions vary substantially, depending on reactions involving HO2 and NO species, and that this can have a noticeable influence on the flowfield. The second part of this study deals with premixed reacting flows under thermal nonequilibrium conditions. Here, the critical problem is coupling of the vibrational relaxation process with the radiative heat transfer. The specific problem considered is a premixed expanding flow in a supersonic nozzle. Results indicate the presence of nonequilibrium conditions in the expansion region of the nozzle. This results in reduction of the radiative interactions in the flowfield. Next, the present study focuses on investigation of non-premixed flows under chemical nonequilibrium conditions. In this case, the main problem is the coupled turbulence-chemistry interaction. The resulting formulation is validated by comparison with experimental data on reacting supersonic coflowing jets. Results indicate that the effect of heat release is to lower the turbulent shear stress and the mean density. The last part of this study proposes a new theoretical formulation for the coupled turbulence-radiation interactions. Results obtained for the coflowing jets experiment indicate that the effect of turbulence is to enhance the radiative interactions. Derived from text

TWO-DIMENSIONAL, HIGH FLOW, PRECISELY CONTROLLED MONODISPERSE DROP SOURCE Final Report, 8 Nov. 1989 - 8 Mar. 1993
John L. Dressler 15 Mar. 1993 62 p
(Contract F33615-89-C-2973)
(AD-A267660; WL-TR-93-2049) Avail: CASI HC A04/MF A01

A versatile acoustically-driven fluid atomizer was designed and operated that creates precise monodisperse sprays by Rayleigh breakup or polydisperse sprays by the acoustic driving of amplitude dependent instabilities. The atomizer forms a cylindrical, conical, or flat (sheet) liquid jet by means of a photofabricated nozzle. The spray pattern and spray volume are altered by changing the nozzle. A piezoelectric driver, constructed to efficiently couple energy to the liquid, modulates the fluid velocity. When operated at low power, the drop generator can produce arrays of monodisperse drops as small as 15 microns in diameter. Operating the piezoelectric driver at high power produces perturbations with sufficient energy to break the liquid jets into drops, with a net increase in surface energy. The resulting drop sizes are influenced by the frequency and amplitude of the driving signal and nozzle size. The spatial distribution of the spray is controlled by the spacing and geometry of the holes in the nozzle plate, the amplitude of the acoustic signal, and the swirl in the fluid manifold. This device is more robust than the typical acoustic drop generator because small drops can be made from large holes, reducing the plugging problem. No air flow is used. DTIC

MULTIGRID TIME-ACCURATE INTEGRATION OF NAVIER-STOKES EQUATIONS
Andrea Arnone (Florence Univ., Italy.), Meng-Sing Liou, and Louis A. Povinelli Nov. 1993 11 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106373; ICOMP-93-37; E-8183; NAS 1.15:106373) Avail: CASI HC A03/MF A01

Efficient acceleration techniques typical of explicit steady-state solvers are extended to time-accurate calculations. Stability restrictions are greatly reduced by means of a fully implicit time discretization. A four-stage Runge-Kutta scheme with local time stepping, residual smoothing, and multigridding is used instead of traditional time-expensive factorizations. Some applications to natural and forced unsteady viscous flows show the capability of the procedure. Author

TRANSITION INDUCED BY FIXED AND FREELY CONVECTING SPHERICAL PARTICLES IN LAMINAR BOUNDARY LAYERS Final Report
H. L. Petrie, P. J. Morris, A. R. Bajwa, and D. C. Vincent Aug. 1993 108 p
(Contract N00014-91-J-1646)
(AD-A267757; TR-93-07) Avail: CASI HC A06/MF A02

An experimental and analytical study of aspects of transition induced by disturbances from spherical particles in laminar boundary layers is discussed. The generation of turbulent wedges by fixed spherical particles in a laminar boundary layer on or near the surface of a flat plate is considered experimentally using flow visualization with fluorescent dye and laser Doppler velocimetry. Turbulent spots generated by freely convecting spherical particles that are released in the freestream to fall into a flat plate laminar boundary layer and impact the plate are also discussed. A combination of dye flow visualization and a video based particle tracking technique was used to study the convecting particle problem. Although the Reynolds number at the critical condition for turbulent wedge generation by fixed particles and turbulent spot generation by convecting particles are similar, transition in these two situations appears to be fundamentally different. The development of a turbulent wedge near the critical condition is a relatively gradual process. In contrast, turbulent spots form relatively quickly after the convecting particles enter the boundary layer and impact the plate. Turbulent wedge formation downstream of a fixed particle results from the destabilization of the near wall flow by the vortical structures shed into particle wake. This shedding process is dominated by periodically shed loop shaped hairpin vortices. Observation of subharmonic oscillations at 1/2 and 1/4 of this shedding frequency suggest that a chaotic route to turbulence by a series of period doubling bifurcations is possible. DTIC

ACTIVE TURBULENCE CONTROL IN WALL BOUNDED FLOWS USING DIRECT NUMERICAL SIMULATION Final Technical Report, 1 Jul. 1989 - 30 Sep. 1992
Parviz Moin 6 Nov. 1992 292 p
(Grant AF-AFOSR-0411-89)
(AD-A267261; AFOSR-93-0467TR) Avail: CASI HC A13/MF A03

The objective of the study is to explore concepts for control of turbulent boundary layers leading to skin-friction reduction using the direct numerical simulation technique. This report is divided into three parts where different control methods are investigated: an active control by sensing and perturbing structures near the wall, a feedback control procedure guided by control theory, and a passive control by longitudinal riblets. Part 1: significant drag reduction is achieved when the surface boundary condition is modified to suppress the dynamically significant coherent structures present in the wall region. Part 2: mathematical methods of control theory are applied to the problem of control of fluid flow. Part 3: direct numerical simulation is performed to analyze turbulent flow over longitudinal riblets, and to reduce the mechanism of drag reduction by riblets. DTIC

THE ROLES OF FLUID MOTION AND OTHER TRANSPORT PHENOMENA IN THE MORPHOLOGY OF MATERIALS Final Report, Sep. 1988 - Dec. 1992
D. A. Saville Nov. 1993 311 p
(Grant NAG8-749)
(NASA-CR-194665; NAS 1.26:194665) Avail: CASI HC A14/MF A03

Two crystallization problems were studied: the growth of protein crystals, in particular the influence of colloidal forces and convection, and the influence of interface resistance on the growth of dendritic crystals. The protein study involved both experimental and theoretical work; the work of dendrites was entirely theoretical. In the study of protein crystallization, experiments were carried out where crystals were grown in the presence and absence of natural convection. No evidence was found that convection retards crystal growth. The theoretical study focused on the influence of colloidal forces (electrostatic and London-van der Waals) on the interaction between a protein molecule and a flat crystal surface. It was shown that the interaction is extremely sensitive to colloidal forces and that electrostatic interactions play a strong role in deciding whether or not a molecule will find a favorable site for adsorption. In the study of dendritic growth, the role of

an interfacial resistance on the selection processes was examined. Using a computational scheme, it was found that the selected velocity is strongly dependent on the magnitude of the interfacial resistance to heat transfer. This is a possible explanation for discrepancies between the theoretical and experimental results on succinonitrile. Author (revised)

A NUMERICAL INVESTIGATION OF ENERGY TRANSFER AND SUBGRID-SCALE EDDY-VISCOSITY IN HOMOGENEOUS, ISOTROPIC, AND SHEAR TURBULENCE Final Report, 15 May 1990 - 31 Aug. 1992

J. A. Domaradzki 20 Sep. 1992 78 p

(Grant AF-AFOSR-0300-90)

(AD-A267265; AFOSR-93-0479TR) Avail: CASI HC A05/MF A01

Using results of direct numerical stimulation we have analyzed nonlinear energy transfer between scales of motion in isotropic and homogeneous shear turbulence in both spectral and physical space representation. In all cases we find that the transfer is local, occurring between similar scales, but is always moderated by scales from the energy containing range (local transfer through nonlocal triad interaction). Such local energy exchanges dominate also subgrid-scale energy transfer which was found to be composed as a forward and an inverse transfer components, both being significant in dynamics of large scales. The spatial structure of the subgrid-scale transfer was compared with the structure of a number of physical quantities which are considered important in the dynamics of large scales giving usually poor correlations. Moderate correlations were observed only for the large scale energy and the Smagorinsky's transfer. Finally, a new theory of spectral energy dynamics was developed. The theory provides a plausible physical mechanism of the observed transfer process and predicts the energy spectrum in the inertial and the dissipation range in agreement with experiments and simulations. ON THE a-POSTERIORI ESTIMATION OF THE MODELLING ERROR FOR THE HEAT CONDUCTION IN A PLATE AND ITS USE FOR ADAPTIVE HIERARCHIC MODELLING Final Report

I. Babuska, I. Lee, and C. Schwab Apr. 1993 30 p

(Contract N00014-90-J-1030)

(AD-A267965; BN-1145) Avail: CASI HC A03/MF A01

The paper addresses the a-posteriori error estimates of modelling heat convection problems in a plate. It derives estimators which are essentially local (of the size of the thickness of the plate). The estimator is guaranteed to be an upper bound. The lower bound of the error is also given. The asymptotic exactness of the estimator with respect to the thickness of the plate and with respect to the order of the model is proven. The adaptive procedure based on this a-posteriori error estimator is proposed. Numerical examples are given. DTIC

TIME DEPENDENT TURBULENCE MODELING AND ANALYTICAL THEORIES OF TURBULENCE

R. Rubinstein Nov. 1993 29 p

(Contract NCC3-233; RTOP 505-90-5K)

(NASA-TM-106379; ICOMP-93-41; CMOTT-93-15; E-8192; NAS 1.15:106379) Avail: CASI HC A03/MF A01

By simplifying the direct interaction approximation (DIA) for turbulent shear flow, time dependent formulas are derived for the Reynolds stresses which can be included in two equation models. The Green's function is treated phenomenologically, however, following Smith and Yakhot, we insist on the short and long time limits required by DIA. For small strain rates, perturbative evaluation of the correlation function yields a time dependent theory which includes normal stress effects in simple shear flows. From this standpoint, the phenomenological Launder-Reece-Rodi model is obtained by replacing the Green's function by its long time limit. Eddy damping corrections to short time behavior initiate too quickly in this model; in contrast, the present theory exhibits strong suppression of eddy damping at short times. A time dependent theory for large strain rates is proposed in which large scales are governed by rapid distortion theory while small scales are governed by Kolmogorov inertial range dynamics. At short times and large strain rates, the theory closely matches rapid distortion theory, but at long times it relaxes to an eddy damping model. Author

CONVECTION EFFECTS ON RADIAL SEGREGATION AND CRYSTAL MELT INTERFACE IN VERTICAL BRIDGMAN GROWTH Final Report

S. Tanveer (Ohio State Univ., Columbus.) Sep. 1993 58 p Submitted for publication

(Contracts NAS1-18605; NAS1-19480; NAG3-1415; NSF DMS-91-07608; RTOP 505-90-52-01)

(NASA-CR-191541; NAS 1.26:191541; ICASE-93-72) Avail: CASI HC A04/MF A01

We analytically study the influence of convection caused by horizontal heat transfer through the sides of a vertical Bridgman apparatus. We consider the case when the heat transfer across the side walls is small so that the resulting interfacial deformation and fluid velocities are also small. This allows us to linearize the Navier-Stokes equations and express the interfacial conditions about a planar interface through a Taylor expansion. Using a no tangential stress conditions on the side walls, asymptotic expressions for both the interfacial slope, and radial segregation at the crystal-melt interface are obtained in closed form in the limit of large thermal Rayleigh number. It is suggested that these can be reduced by appropriately controlling a specific heat transfer property at the edge of the insulation zone in the solid side. Author

OPTIMIZATION OF TWO-STAGE HOT WATER EXCHANGE POINTS [OPTYMALIZACJA WYMIENNIKOWYCH DWUSTOPNIOWYCH WEZLOW CIEPLEJ WODY]

Mariusz Adamski 1991 21 p In POLISH

Avail: CASI HC A03/MF A01

This paper presents a method of optimizing the components in hot water heat exchangers. A mathematical model is developed for both the operation of serial-parallel as well as serial-serial heat exchangers. Primary attention is devoted to the operation of the components in the maximum water consumption range. Optimization of the components makes it possible to establish the mean hot water temperature guaranteeing minimum surface area of the heat exchangers. Transl. by FLS

BOUNDARY CONDITIONS AND THE SIMULATION OF LOW MACH NUMBER FLOWS

Thomas Hagstrom and Jens Lorenz (New Mexico Univ., Albuquerque.) Nov. 1993 15 p

(Contracts NCC3-233; DE-FG03-92ER-25128; NSF DMS-91-08072; NSF DMS-91-07612)

(NASA-TM-106374; ICOMP-93-38; E-8184; NAS 1.15:106374) Avail: CASI HC A03/MF A01

The problem of accurately computing low Mach number flows, with the specific intent of studying the interaction of sound waves with incompressible flow structures, such as concentrations of vorticity is considered. This is a multiple time (and/or space) scales problem, leading to various difficulties in the design of numerical methods. Concentration is on one of these

difficulties - the development of boundary conditions at artificial boundaries which allow sound waves and vortices to radiate to the far field. Nonlinear model equations are derived based on assumptions about the scaling of the variables. Then these are linearized about a uniform flow and exact boundary conditions are systematically derived using transform methods. Finally, useful approximations to the exact conditions which are valid for small Mach number and small viscosity are computed. Author (revised)

ON THE STABILITY OF A TIME DEPENDENT BOUNDARY LAYER Final Report
S. R. Otto Sep. 1993 37 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191542; NAS 1.26:191542; ICASE-93-73) Avail: CASI HC A03/MF A01

The aim of this article is to determine the stability characteristics of a Rayleigh layer, which is known to occur when the fluid above a flat plate has a velocity imparted to it (parallel to the plate). This situation is intrinsically unsteady, however, as a first approximation we consider the instantaneous stability of the flow. The Orr-Sommerfeld equation is found to govern fixed downstream wavelength linear perturbations to the basic flow profile. By the solution of this equation, we can determine the Reynolds numbers at which the flow is neutrally stable; this quasisteady approach is only formally applicable for infinite Reynolds numbers. We shall consider the large Reynolds number limit of the original problem and use a three deck mentality to determine the form of the modes. The results of the two calculations are compared, and the linear large Reynolds number analysis is extended to consider the effect of weak nonlinearity in order to determine whether the system is subcritical or supercritical. SINGLE BLOCK THREE-DIMENSIONAL VOLUME GRIDS ABOUT COMPLEX AERODYNAMIC VEHICLES
Stephen J. Alter (Lockheed Engineering and Sciences Co., Hampton, VA.) and K. James Weilmuenster Nov. 1993 50 p
(RTOP 506-40-91-02)
(NASA-TM-108986; NAS 1.15:108986) Avail: CASI HC A03/MF A01

This paper presents an alternate approach for the generation of volumetric grids for supersonic and hypersonic flows about complex configurations. The method uses parametric two dimensional block face grid definition within the framework of GRIDGEN2D. The incorporation of face decomposition reduces complex surfaces to simple shapes. These simple shapes are combined to obtain the final face definition. The advantages of this method include the reduction of overall grid generation time through the use of vectorized computer code, the elimination of the need to generate matching block faces, and the implementation of simplified boundary conditions. A simple axisymmetric grid is used to illustrate this method. In addition, volume grids for two complex configurations, the Langley Lifting Body (HL-20) and the Space Shuttle Orbiter, are shown. Avail: CASI HC A03/MF A01

NASA Lewis Research has been investigating the no-vent fill method, since it is a promising approach to transfer liquid while handling the problems of low-g venting. This paper reports the results of a test series for filling a 71 cu ft tank with liquid hydrogen without venting. 22 tests were conducted, 10 with a bottom orifice as the inlet and 12 with a spray bar. Parameters investigated included inlet saturation pressures of approximately 5, 15, and 25 psia, transfer pressures of 20, 30, and 45 psia, and various starting wall temperatures. Of the tests, only the one run at the highest wall temperature (238 R) failed to fill the tank. Test results are compared to a thermodynamic equilibrium model. Overall model-data agreement was good except for the tendency of the model to overshoot during the initial wall cool down of the higher starting wall temperature fills. Author

COMPRESSIBLE FLOW SOLVERS USING UNSTRUCTURED GRIDS
Alain Dervieux and Jean-Antoine Desideri Jun. 1992 116 p
(INRIA-RR-1732; ETN-93-94434) Avail: CASI HC A06/MF A02

A detailed review of works related to the MUSCL FEM (Finite Element Method) upwind method for unstructured meshes is presented. Because the discrete geometry (triangulation, tetrahedrization) will likely be irregular, it is chosen to derive the approximation from both recent techniques in upwind TVD finite volume and FE in order to get an accurate, robust, and parameter free discrete model. As a result of this strategy the codes may be very time consuming, and focus is given to the important issue of efficiency. Some recent developments in mesh adaption techniques are also addressed. A DOMAIN-PARTITION METHOD FOR THE ADVECTION-DIFFUSION EQUATION Thesis [UNE METHODE DE PARTITION DE DOMAINE POUR L'EQUATION D'ADVECTION-DIFFUSION]
Pierre Aubert, Marie-Claude Ciccoli, and Jean-Antoine Desideri Aug. 1992 47 p In FRENCH
(INRIA-RR-1740; ETN-93-94436) Avail: CASI HC A03/MF A01

A report corresponding to a manuscript for the degree of DEA is presented. The objective of the study was to formalize a domain partition method for a linear advection diffusion model problem, to demonstrate the properties of the basic algorithms, and thus prepare future tests of novel algorithms in a simplified context. From a technical standpoint, domain decomposition methods in general (using partition or overlapping) for the solution of partial differential equations are currently regaining interest because they are naturally adapted to parallel computing. The computational domain is decomposed in subdomains over which subproblems of reduced size are solved simultaneously and coupled iteratively to enforce matching conditions at the interfaces. A theoretical presentation of a domain partition method for the advection diffusion equation in one and two space dimensions, and numerical results, are presented. ESA

MULTIGRID DIRECT NUMERICAL SIMULATION OF THE WHOLE PROCESS OF FLOW TRANSITION IN 3-D BOUNDARY LAYERS
Chaoqun Liu and Zhining Liu (Colorado Univ., Denver.) Nov. 1993 40 p
(Contracts NAS1-10312; NCC3-233; RTOP 505-90-5K)
(NASA-TM-106369; ICOMP-93-36; E-8175; NAS 1.15:106369; CMOTT-93-13) Avail: CASI HC A03/MF A01

A new technology was developed in this study which provides a successful numerical simulation of the whole process of flow transition in 3-D boundary layers, including linear growth, secondary instability, breakdown, and transition at relatively low CPU cost. Most other spatial numerical simulations require high CPU cost and blow up at the stage of

flow breakdown. A fourth-order finite difference scheme on stretched and staggered grids, a fully implicit time marching technique, a semi-coarsening multigrid based on the so-called approximate line-box relaxation, and a buffer domain for the outflow boundary conditions were all used for high-order accuracy, good stability, and fast convergence. A new fine-coarse-fine grid mapping technique was developed to keep the code running after the laminar flow breaks down. The computational results are in good agreement with linear stability theory, secondary instability theory, and some experiments. The cost for a typical case with 162 x 34 x 34 grid is around 2 CRAY-YMP CPU hours for 10 T-S periods. Author

GRAVITY DEPENDENT CONDENSATION PRESSURE DROP AND HEAT TRANSFER IN AMMONIA TWO-PHASE HEAT TRANSPORT SYSTEMS

A. A. M. Delil 1 Apr. 1992 11 p Presented at 1992 National Heat Transfer Conference AIAA Session on Phase Change Heat Transfer, San Diego, CA, 9-12 Aug. 1992 See also A92-56140

(NLR-TP-92121-U; AIAA Paper 92-4057; ETN-93-94787) Avail: CASI HC A03/MF A01

Results of calculations on condensing flow in a straight condenser duct, which investigated the impact of (reduced) gravity on the duct length required to achieve complete condensation, are reported. Condensers are critical components in two phase heat transport systems envisaged for future large spacecraft. In order to properly design such condensers, experimental data obtained from ground testing and reduced gravity aircraft and rocket flight testing, plus results of thermal modeling and scaling calculations are used. The result of such activities, frequently reported in the literature, is that condensation lengths required in low gravity environment exceed the corresponding lengths on Earth (in horizontal ducts) by at least one order of magnitude, while the accompanying pressure drops are almost the same. As the flow patterns are different in both situations, it was considered to be a better approach to theoretically (and later also experimentally) investigate the impact of gravity on condensation pressure drops and heat transfer for an identical flow pattern, namely annual-wavy-mist observed for vapor qualities ranging from 1 down to values below 0.1 (hence, almost the entire condensation length), both for low gravity conditions and for vertical downflow in a gravity field. The results of this approach are discussed for condensers using ammonia as the working fluid. ESA

STUDY INTO THE LIMITS OF AN EULER EQUATION METHOD APPLIED TO LEADING-EDGE VORTEX FLOW

J. I. vandenBerg, H. W. M. Hoeijmakers, and H. A. Sytsma 9 Sep. 1991 12 p Presented at 9th GAMM Conference on Numerical Methods in Fluid Mechanics, Lausanne, Switzerland, 25-27 Sep. 1991 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract NIVR-07701N)

(NLR-TP-91350-U; ETN-93-94781) Avail: CASI HC A03

A steady fow Euler method is applied to the subsonic leading edge vortex flow about a 65 deg sharp-edged cropped delta wing at high incidence. Above a critical value of the incidence the numerical procedure fails to fully converge, the solution at successive iterations exhibiting a behavior similar to the one observed during vortex breakdown. The occurrence of this 'solution breakdown' indicates the limits of the domain of applicability of the steady flow Euler method for the case of subsonic leading edge vortex flow. Analysis of the solution at incidences just below the critical value reveals that a bubble type of flow feature develops within the vortex core. ESA

Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC

A balance is disclosed for an apparatus for measuring the various aerodynamic coefficients of flight vehicles by testing scale models of these vehicles in a wind tunnel. The balance of the invention measures the following parameters: axial, normal, and side force; and pitching, yawing, and rolling moments. The balance is based on a monopiece center core where sensing components have a roll or primary frame as well as being reference supports to strain gauges. The dual function of the primary frame means that forces and moments, when applied to the balance, will generate interferences in several other components. Because of the center core configuration, it is possible to calibrate, calculate, and deduct with a very high precision the interferences of each component over the other. Except for the axial force sensing components, all forces and moments are sensed by two groups of crossed webs, one cross web at each end of the center core. The axial force sensing components are made of two tensioning rings, one at each end of the center core. The configuration of the balance is of the rigid-frame type, in order to make use of semiconductor strain gauges which are very precise. The resulting balance is more precise than any known balance of its size and can resist starting and stopping overloads which occur at the beginning and end of a test. Author (CISTI)

SIMULTANEOUS MEASUREMENT OF TEMPERATURE AND STRAIN USING FOUR CONNECTING WIRES

Allen R. Parker, Jr. Nov. 1993 10 p Presented at SEM Fall Conference and Exhibit on Structural Testing Technology at High Temperature-II, Ojai, CA, 8 Nov. 1993

(RTOP 505-70-63)

(NASA-TM-104271; H-1945; NAS 1.15:104271) Avail: CASI HC A02/MF A01

This paper describes a new signal-conditioning technique for measuring strain and temperature which uses fewer connecting wires than conventional techniques. Simultaneous measurement of temperature and strain has been achieved by using thermocouple wire to connect strain gages to signal conditioning. This signal conditioning uses a new method for demultiplexing sampled analog signals and the Anderson current loop circuit. Theory is presented along with data to confirm that strain gage resistance change is sensed without appreciable error because of thermoelectric effects. Furthermore, temperature is sensed without appreciable error because of voltage drops caused by strain gage excitation current flowing through the gage resistance. Author (revised)

NASA's robotic solar system exploration program requires a new generation of science instruments. Design concepts are now judged against stringent mass, power, and size constraints--yet future instruments must be highly capable, reliable, and, in some applications, they must operate for many years. The most important single constraint, however, is cost: new instruments must be developed in a tightly controlled design-to-cost environment. Technical innovation is the key to success and will enable the sophisticated measurements needed for future scientific exploration. As a fundamental benefit, the incorporation of breakthrough technologies in planetary flight hardware will contribute to U.S. industrial competitiveness and will strengthen the U.S. technology base. The Workshop on Advanced Technologies for Planetary Instruments was conceived to address these challenges, to provide an open forum in which the NASA and DoD space communities could become better acquainted at the working level, and to assess future collaborative efforts. Over 300 space scientists and engineers participated in the two-and-a-half-day meeting held April 28-30, 1993, in Fairfax, Virginia. It was jointly sponsored by NASA's Solar System Exploration

Division (SSED), within the Office of Space Science (OSS); NASA's Office of Advanced Concepts and Technology (OACT); DoD's Strategic Defense Initiative Organization (SDIO), now called the Ballistic Missile Defense Organization (BMDO); and the Lunar and Planetary Institute (LPI). The meeting included invited oral and contributed poster presentations, working group sessions in four sub-disciplines, and a wrap-up panel discussion. On the first day, the planetary science community described instrumentation needed for missions that may go into development during the next 5 to 10 years. Most of the second day was set aside for the DoD community to inform their counterparts in planetary science about their interests and capabilities, and to describe the BMDO technology base, flight programs, and future directions. The working group sessions and the panel discussion synthesized technical and programmatic issues from all the presentations, with a specific goal of assessing the applicability of BMDO technologies to science instrumentation for planetary exploration. AN ELECTRONIC IMAGING SYSTEM FOR THE AEROBALLISTIC RESEARCH FACILITY Final Report
G. L. Winchenbach, D. B. Snyder, M. A. Valentino, H. C. Macke, and W. J. Rowe Jul. 1993 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267157; WL-TP-93-002) Avail: CASI HC A03

Until the present date, free-flight spark ranges used conventional film technology for recording the position-attitude histories of the projectiles as they traversed the instrumented ranges. The purpose is to describe the plans for converting the existing film based camera system in the Aeroballistic Research Facility to an electronic imaging system based on modern charge coupled device (CCD) technology. The primary concern associated with this conversion was always maintaining the facility's accuracy in measuring the projectile's position and attitude at each of the shadowgraph stations. This accuracy is directly related to the resolution of the CCD, i.e., number of pixels. Some other concerns were minimizing the facility down-time while the new imaging system is installed and maintaining a means of analyzing previous film exposures captured during the past 15 years of operation. The solution to these concerns is the development of a film reader system which also uses a CCD type camera to digitize the existing film. DTIC

CAPACIFLECTOR CAMERA Patent Application
John M. Vranish, inventor (to NASA) 12 Jul. 1993 39 p
(NASA-Case-GSC-13564-1; NAS 1.71:GSC-13564-1;
US-Patent-Appl-SN-090230) Avail: CASI HC A03/MF A01

A capacitive type proximity sensor having improved range and sensitivity between a surface and an intruding object in the vicinity of the surface having a voltage source, a number of outer electrical conductors on the surface with each forming one electrode of a number of sensor capacitors, the other electrode for each sensor capacitor being the object is described. The outer conductors are made from thin sheets of conductive material covered with insulation. An intermediate electrical conductor is located between the outer conductors and the surface and is of a size larger than the outer conductors to act as a shield for reducing the parasitic capacitance between the outer conductors and the surface. The intermediate conductor is also made from a thin sheet of conductive material covered with insulation. The outer conductors and the intermediate conductor are attached to the surface with no gap between the insulation on the conductors and no gap between the surface and the insulation on intermediate conductor, the outer conductors and the intermediate conductor conjoining with each other and with the surface, with the surface acting as a ground plane. A current-measuring voltage follower circuit is connected to the voltage source for coupling in phase and amplitude the instantaneous voltage at the voltage source to the outer electrical conductors and the intermediate electrical conductor. This circuit is responsive to the change in capacitance of the sensor capacitors and generates a number of output signals. NASA

SUPERCONDUCTIVE MATERIAL AND MAGNETIC FIELD FOR DAMPING AND LEVITATION SUPPORT AND DAMPING OF CRYOGENIC INSTRUMENTS Patent Application
Benjamin P. Dolgin, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 15 Jun. 1993 14 p
(Contract NAS7-918)
(NASA-Case-NPO-18458-1-CU; NAS 1.71:NPO-18458-1-CU;
US-Patent-Appl-SN-077470) Avail: CASI HC A03/MF A01

A superconductive load bearing support without a mechanical contact and vibration damping for cryogenic instruments in space is presented. The levitation support and vibration damping is accomplished by the use of superconducting magnets and the 'Meissner' effect. The assembly allows for transfer of vibration energy away from the cryogenic instrument which then can be damped by the use of either an electronic circuit or conventional vibration damping mean. IMPROVEMENTS TO PULSED PHASE LOCKED LOOP STRAIN MONITOR Patent Application
Mark E. Froggatt, inventor (to NASA) 12 Aug. 1993 58 p
(NASA-Case-LAR-14887-1; NAS 1.71:LAR-14887-1;
US-Patent-Appl-SN-105161) Avail: CASI HC A04/MF A01

A pulse phase locked loop system according to the present invention is described. A frequency generator such as a voltage controlled oscillator (VCO) generates an output signal and a reference signal having a frequency equal to that of the output signal. A transmitting gate gates the output frequency signal and this gated signal drives a transmitting transducer which transmits an acoustic wave through a material. A sample/hold samples a signal indicative of the transmitted wave which is received by a receiving transducer. Divide-by-n counters control these gating and sampling functions in response to the reference signal of the frequency generator. Specifically, the output signal is gated at a rate of F/h, wherein F is the frequency of the output signal and h is an integer; and the received signal is sampled at a delay of F/n wherein n is an integer. REMOTE TIRE PRESSURE SENSING TECHNIQUE Patent Application
Howard H. Robinson, inventor (to NASA), Timothy A. McGinnis, inventor (to NASA) (Wyle Labs., Inc., Hampton, VA.), and Robert H. Daugherty, inventor (to NASA) 23 Aug. 1993 9 p
(NASA-Case-LAR-14160-1; NAS 1.71:LAR-14160-1;
US-Patent-Appl-SN-111321) Avail: CASI HC A02/MF A01

A remote tire pressure sensing technique is provided which uses vibration frequency to determine tire pressure. A vibration frequency measuring device is attached to the external surface of a tire which is then struck with an object, causing the tire to vibrate. The frequency measuring device measures the vibrations and converts the vibrations into corresponding electrical impulses. The electrical impulses are then fed into the frequency analyzing system which uses the electrical impulses to determine the relative peaks of the vibration frequencies as detected by the frequency measuring device. The measured vibration frequency peaks are then compared to predetermined data describing the location of vibration frequency peaks for a given pressure, thereby determining the air pressure of the tire. DUAL ACTIVE SURFACE, MINIATURE, PLUG-TYPE HEAT FLUX GAUGE Patent Application
Curt H. Liebert, inventor (to NASA) and John Koch, Jr., inventor (to NASA) 16 Apr. 1993 15 p
(NASA-Case-LEW-15643-1; NAS 1.71:LEW-15643-1;
US-Patent-Appl-SN-047120) Avail: CASI HC A03/MF A01

A plug-type heat flux gauge can simultaneously measure heat flux on two opposite surfaces of thick or very thin convection or impingement cooled metal walls. The gauge is capable of continuously measuring transient and steady heat flux under transient and steady state gauge temperature operating conditions. The length of the gauge extends through the entire

thickness of the material. A non-linear temperature gradient through the gauge can be measured by attaching 3-5 thermocouples along the length of the gauge. NASA

NEURAL-NETWORK-DIRECTED ALIGNMENT OF OPTICAL SYSTEMS USING THE LASER-BEAM SPATIAL FILTER AS AN EXAMPLE
Arthur J. Decker, Michael J. Krasowski, and Kenneth E. Weiland Aug. 1993 33 p Sponsored by NASA. Washington
(RTOP 590-21-11)
(NASA-TP-3372; E-7524; NAS 1.60:3372) Avail: CASI HC A03/MF A01

This report describes an effort at NASA Lewis Research Center to use artificial neural networks to automate the alignment and control of optical measurement systems. Specifically, it addresses the use of commercially available neural network software and hardware to direct alignments of the common laser-beam-smoothing spatial filter. The report presents a general approach for designing alignment records and combining these into training sets to teach optical alignment functions to neural networks and discusses the use of these training sets to train several types of neural networks. Neural network configurations used include the adaptive resonance network, the back-propagation-trained network, and the counter-propagation network. This work shows that neural networks can be used to produce robust sequencers. These sequencers can learn by example to execute the step-by-step procedures of optical alignment and also can learn adaptively to correct for environmentally induced misalignment. The long-range objective is to use neural networks to automate the alignment and operation of optical measurement systems in remote, harsh, or dangerous aerospace environments. This work also shows that when neural networks are trained by a human operator, training sets should be recorded, training should be executed, and testing should be done in a manner that does not depend on intellectual judgments of the human operator. EFFECTS OF WINDOW SIZE AND SHAPE ON ACCURACY OF SUBPIXEL CENTROID ESTIMATION OF TARGET IMAGES
Sharon S. Welch Washington Oct. 1993 37 p
(RTOP-590-14-11-02)
(NASA-TP-3331; L-17113; NAS 1.60:3331) Avail: CASI HC A03/MF A01

A new algorithm is presented for increasing the accuracy of subpixel centroid estimation of (nearly) point target images in cases where the signal-to-noise ratio is low and the signal amplitude and shape vary from frame to frame. In the algorithm, the centroid is calculated over a data window that is matched in width to the image distribution. Fourier analysis is used to explain the dependency of the centroid estimate on the size of the data window, and simulation and experimental results are presented which demonstrate the effects of window size for two different noise models. The effects of window shape were also investigated for uniform and Gaussian-shaped windows. The new algorithm was developed to improve the dynamic range of a close-range photogrammetric tracking system that provides feedback for control of a large gap magnetic suspension system (LGMSS). TEMPERATURE AND PRESSURE EFFECTS ON CAPACITANCE PROBE CRYOGENIC LIQUID LEVEL MEASUREMENT ACCURACY Final Report
Lawrence G. Edwards and Mark Haberbusch (Ohio Aerospace Inst., Brook Park.) Sep. 1993 32 p Presented at the 39th International Instrumentation Symposium, Albuquerque, NM, 3-6 May 1993
(Contract NAS3-25776; RTOP 506-42-00)
(NASA-CR-190763; E-8122; NAS 1.26:190763) Avail: CASI HC A03/MF A01

The inaccuracies of liquid nitrogen and liquid hydrogen level measurements by use of a coaxial capacitance probe were investigated as a function of fluid temperatures and pressures. Significant liquid level measurement errors were found to occur due to the changes in the fluids dielectric constants which develop over the operating temperature and pressure ranges of the cryogenic storage tanks. The level measurement inaccuracies can be reduced by using fluid dielectric correction factors based on measured fluid temperatures and pressures. The errors in the corrected liquid level measurements were estimated based on the reported calibration errors of the temperature and pressure measurement systems. Experimental liquid nitrogen (LN2) and liquid hydrogen (LH2) level measurements were obtained using the calibrated capacitance probe equations and also by the dielectric constant correction factor method. The liquid levels obtained by the capacitance probe for the two methods were compared with the liquid level estimated from the fluid temperature profiles. Results show that the dielectric constant corrected liquid levels agreed within 0.5 percent of the temperature profile estimated liquid level. The uncorrected dielectric constant capacitance liquid level measurements deviated from the temperature profile level by more than 5 percent. This paper identifies the magnitude of liquid level measurement error that can occur for LN2 and LH2 fluids due to temperature and pressure effects on the dielectric constants over the tank storage conditions from 5 to 40 psia. A method of reducing the level measurement errors by using dielectric constant correction factors based on fluid temperature and pressure measurements is derived. The improved accuracy by use of the correction factors is experimentally verified by comparing liquid levels derived from fluid temperature profiles. Author

This invention is a method and apparatus to use an Atomic Force Microscope to take measurements of surface forces, indentation, adhesion and mechanical properties such as hardness and elasticity. The force between a probe mounted cantilever and a sample is measured as a

function cantilever deflection measured by a electron tunneling microscope. The sample and the tip of the tunneling microscope are each mounted on piezoelectric manipulators which provide for position control. Position of the sample and probe are measured from the voltages applied to the piezoelectric manipulators. Penetration is determined by the relative motion between the probe and sample. Presently, this invention has a force resolution of 1 nm and a depth resolution of 0.02 nm. DTIC

DISPLAY OF DYNAMIC, VOLUME GRAPHIC IMAGES BY HOLOGRAPHIC VOXEL PROJECTION: INITIAL INVESTIGATION Interim Report, Aug. 1989 - Jun. 1991
Shawn L. Kelly and Charles T. Robinson 29 Apr. 1993 51 p
(AD-A267622; WL-TR-93-1059) Avail: CASI HC A04/MF A01

This document presents in-house research on a holographic projector. This device operates by optically guiding the light from each pixel on an internal two dimensional display to a unique focus in a three dimensional volume. Properly addressing the 2-D pixel array via conventional computer graphics equipment will, therefore, generate transparent 3-D images which appear to float in space in front of the observer. A detailed mathematical model was created and used to design the holographic projector and simulate it's operation. Proof-of-concept experiments were conducted to test the capability of holographic materials to provide the performance predicted by the model. The results of this initial investigation support the continuation of research and development of the holographic projector as a special display for applications such as threat warning or directional indication. FREQUENCY RESOLUTION OF AN ACOUSTO-OPTICAL SPECTROMETER
Jing-Sheng Wang and Jian-Jun Shen 3 Aug. 1993 16 p Transl. into ENGLISH from Shengxue Xuebao (China), v. 15, no. 4, Jul. 1990 p 299-303
(AD-A267822; FASTC-ID(RS)T-0219-93) Avail: CASI HC A03/MF A01

This paper discusses the frequency resolution of an acousto-optical spectrometer (AOS) system as affected by the acousto-optical deflector and the coherent light beam truncation ratio and examines the response of the photodiode array reception system as affected by the AOS frequency resolution. The broadening of the resolution line pattern caused by the response of a photodiode pixel was computed. From this discussion, the authors proposed selection principles for AOS design parameters, including the light beam truncation ratio, focal length of the Fourier lens, and the number of photodiode array elements. These principles include the overall consideration of resolution, frequency bandwidth, and side lobes of the instrument profile in order to enable the AOS to be designed on a quantitative basis that is suitable to specific observational requirements. To verify these theoretical calculations, the frequency resolution was experimentally measured. DTIC

STUDY OF HIGH SPEED INTERFERENCE PHOTOGRAPHY WITH TWO-DIMENSIONAL ACOUSTO-OPTICAL LATTICE DEFLECTION
Anzhi He, Da-Peng Yan, and Xiao-Wu Ni 20 Jul. 1993 15 p Transl. into ENGLISH from Guangxue Xuebao (China), v. 11, no. 4, Apr. 1991 p 364-368
(AD-A267823; FASTC-ID(RS)T-0221-93) Avail: CASI HC A03/MF A01

This paper presents the principle and method of high speed interference photography by using the technique of two dimensional acousto-optical lattice deflection. The light beam carrying the interferogram is deflected into a lattice of 10x10 light spots in a time series; the interferogram is recorded on a photographic negative. The cw laser is the light source; the exposure time can be adjusted between 10(exp -5) to approximately 3(10)(exp -6) s; the framing frequency was about 10(exp 5) frames/s. This method was used to record interferograms of transient-state temperature fields in an experimental study of the principle. DTIC

CRYOGENIC SPRAY VAPORIZATION IN HIGH-VELOCITY HELIUM, ARGON AND NITROGEN GASFLOWS
Robert D. Ingebo Oct. 1993 13 p Proposed for presentation at the AIAA 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 505-62-52)
(NASA-TM-106363; E-8161; NAS 1.15:106363; AIAA Paper 94-0687)
Avail: CASI HC A03/MF A01

Effects of gas properties on cryogenic liquid-jet atomization in high-velocity helium, nitrogen, and argon gas flows were investigated. Volume median diameter, D(sub v.5e), data were obtained with a scattered-light scanning instrument. By calculating the change in spray drop size, -Delta D(sub v.5)(exp 2), due to droplet vaporization, it was possible to calculate D(sub v.5C). D(sub v.5C) is the unvaporized characteristic drop size formed at the fuel-nozzle orifice. This drop size was normalized with respect to liquid-jet diameter, D(sub O). It was then correlated with several dimensionless groups to give an expression for the volume median diameter of cryogenic LN2 sprays. This expression correlates drop size D(sub v.5c) with aerodynamic and liquid-surface forces so that it can be readily determined in the design of multiphase-flow propellant injectors for rocket combustors. MONTE CARLO SIMULATION OF THE MICROSTRIP GAS COUNTER
J. Schmitz 1993 8 p Presented at International Conference on Monte Carlo Simulation in High Energy and Nuclear Physics Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NIKHEF-H/93-07; ETN-93-94828) Avail: CASI HC A02

A Monte Carlo simulation to describe the microstrip gas counter is written. The simulation describes ionization, diffusion and gas amplification. Tuning of the Monte Carlo simulation on data from test beam measurements is discussed. The simulation reproduces the performance of the detector as measured in a beam test for perpendicularly incident particles. The large number of free parameters in the simulation leaves place for further optimization using dedicated measurements. It was found that the position resolution in current prototypes is dominated by the sampling error introduced

because the anode distance is larger than the radius of the electron cloud. This can be overcome by geometrical changes, leading to a resolution predicted to be of the order of 20 microns. ESA

RESIST PERFORMANCE IN SOFT X RAY PROJECTION LITHOGRAPHY
G. D. Kubiak (Sandia National Labs., Livermore, CA.), D. A. Tichenor (Sandia National Labs., Livermore, CA.), W. W. Chow, W. C. Sweatt, and M. D. Himel (Bell Telephone Labs., Inc., Holmdel, NJ.) 1993 12 p Presented at the SPIE Meeting on Microlithography, San Jose, CA, 28 Feb. - 5 Mar. 1993
(Contract DE-AC04-76DP-00789)
(DE93-016490; SAND-93-8541C; CONF-9302130-1) Avail: CASI HC A03/MF A01

An important issue for resists used in soft x-ray projection lithography (SXPL) is high absorption. Absorption coefficients of both organic and inorganic formulations range from 2-6 (mu)m(sup (minus)1), requiring the use of very thin (50-100 nm) layers to avoid excessive absorption and resulting pattern sidewall degradation. Such thin films are typically used as the imaging layer in a bi- or tri-level processing scheme to achieve the required pattern depth. In this work, we report experimental and theoretical studies of imaging performance in the resists PMMA and SAL 601 at an SXPL exposure wavelength of 13.9 nm. Absorption coefficients (alpha) have been measured for, and SXPL images recorded in both of these resists. A Mo/Si multilayer-coated Schwarzschild objective having known aberrations and illuminated by a laser plasma soft x-ray source has been used to produce images. Calculated aberrated aerial images are used in conjunction with the measured values of (alpha) to model the expected resist profiles and these are compared to experiment. Imaging performance as a function of resist absorption and estimates of resist exposure latitude are also discussed. DOE

NONINTRUSIVE FAST RESPONSE OXYGEN MONITORING SYSTEM FOR HIGH TEMPERATURE FLOWS Final Report
Daniel B. Oh and Alan C. Stanton Oct. 1993 61 p
(Contract NAS1-19097; SBIR-02.11-1322; RTOP 324-02-01)
(NASA-CR-4553; NAS 1.26:4553) Avail: CASI HC A04/MF A01

A new technique has been developed for nonintrusive in situ measurement of oxygen concentration, gas temperature, and flow velocity of the test media in hypersonic wind tunnels. It is based on absorption of near-infrared radiation from inexpensive GaAlAs laser diodes used in optoelectronics industry. It is designed for simultaneous measurements along multiple lines of sight accessed by fiber optics. Molecular oxygen concentration is measured from the magnitude of absorption signals; rotational gas temperature is measured from the intensity ratio of two oxygen absorption lines; and the flow velocity is measured from the Doppler shift of the absorption line positions. This report describes the results of an extensive series of tests of the prototype instrument in laboratory flames emphasizing assessment of the instruments capabilities for quantitative measurement of O2 concentration (mole fraction) and gas temperature.

New measurements of the stimulated recombinations of electrons and

protons to form hydrogen atoms in states n = 11, 12, and 13 are presented. Measurements have also been made for the stimulated recombination of electrons and He(+) to form n = 15 and n = 16 states. These cross sections show structure due to singlet and triplet capture. The effects of laser radiation on the dissociative recombination of molecular ions H3(+) have been examined, and the results are reported. DTIC

HETERODYNE EFFICIENCY FOR A COHERENT LASER RADAR WITH DIFFUSE OR AEROSOL TARGETS

R. G. Frehlich 26 Oct. 1993 23 p Sponsored in part by NSF
(Grant NAG8-253)
(NASA-CR-194563; NAS 1.26:194563) Avail: CASI HC A03/MF A01

The performance of a Coherent Laser Radar is determined by the statistics of the coherent Doppler signal. The heterodyne efficiency is an excellent indication of performance because it is an absolute measure of beam alignment and is independent of the transmitter power, the target backscatter coefficient, the atmospheric attenuation, and the detector quantum efficiency and gain. The theoretical calculation of heterodyne efficiency for an optimal monostatic lidar with a circular aperture and Gaussian transmit laser is presented including beam misalignment in the far-field and near-field regimes. The statistical behavior of estimates of the heterodyne efficiency using a calibration hard target are considered. For space based applications, a biased estimate of heterodyne efficiency is proposed that removes the variability due to the random surface return but retains the sensitivity to misalignment. Physical insight is provided by simulation of the fields on the detector surface. The required detector calibration is also discussed. Author

GROWTH OF NEW MATERIALS FOR SOLID STATE LASER APPLICATIONS. THE GROWTH OF ZnGeP2 BY THE VERTICAL BRIDGMAN METHOD Final Technical Report, 1 Sep. 1986 - 31 Mar. 1991

R. S. Feigelson 28 Oct. 1993 30 p
(Grant NAG1-698)
(NASA-CR-194571; NAS 1.26:194571; CMR-93-3; SPO-3952) Avail: CASI HC A03/MF A01

This is the final technical report on the cooperative NASA program 'Growth of New Materials for Solid State Laser Applications,' covering the period from 9-1-86 through 3-31-91. The first two and one half years of the program, from 9-1-86 through 3-31-89, was devoted to the development of new eye-safe laser sources. Single crystal fibers of rare earth doped and co-doped YAG were grown by the laser-heated pedestal growth method, characterized for their structural properties and supplied to NASA/Langley for spectroscopic evaluation. From 4-1-89 though 3-31-91, research focused on the growth of zinc germanium phosphide for nonlinear optical applications in the IR. The vertical Bridgman growth process was evaluated as a means to achieve better control over the short wavelength optical absorption in this material that adversely affects 2 micron-pumped optical parametric oscillators. X RAY LASER PROGRAM Final Report, 1 Oct. 1991 - 30 Sep. 1992

John P. Apruzese 1 Jul. 1993 86 p
(AD-A267075; NRL/MR/6721-93-7312) Avail: CASI HC A05/MF A01

This report details the progress achieved by the Radiation Hydrodynamics Branch in X-Ray Laser experiments and modeling during FY-92. Some of the experimental work discussed was carried out at Sandia National Laboratories in collaboration with NRL. It is divided into an executive summary and sections whose authors are separately identified. The individual sections describe progress in the following areas: photopumped x-ray laser research; calculations of x-ray inversions, intensities, and pulsewidths in plasmas created by ultraintense subpicosecond lasers; and effects of non-Maxwellian electron distributions on x-ray gain. DTIC

LASER-SHOCK DAMAGE OF IRON-BASED MATERIALS Final Report, 1990 - 1993

Jinn P. Chu, Grzegorz Banas, Frederick V. Lawrence, James M. Rigsbee, and Hani E. Elsayed-Ali 30 May 1993 156 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0185-90)
(AD-A267196; AFOSR-93-0456TR) Avail: CASI HC A08

The effects of laser shock processing on the microstructure and mechanical properties of the manganese (1 percent C and 14 percent Mn) steels have been low carbon (0.04 wt. percent C) and Hadfield studied. Laser shock processing was performed with a 1.054 micrometers wavelength Nd-phosphate laser operating in a pulse mode (600 ps pulse length and up to 200 J energy) with power densities above 10 to the 11th power W/cm2. Shock waves were generated by volume expansion of the plasma formed when the material was laser irradiated. Maximum shock wave intensities were obtained using an energy-absorbing black paint coating without a plasma-confining overlay. Maximum modification of compressive residual stresses were achieved when laser shock processing induced deformation occurred without melting. Mechanical properties were improved through modifying the microstructure by laser shock processing. High density arrays of dislocations (greater than 10 to the 11th power/cm2) were generated in low carbon steel by high strain-rate deformation of laser shock processing, resulting in surface hardness increases of 30 to 80 percent. In austenitic Hadfield steel, laser shock processing caused extensive formation of Epsilon-hcp martensite (35 vol. percent), producing increases of 50 to 130 percent in surface hardness. The laser shock processing strengthening effect in Hadfield steel was attributed to the combined effects of the partial dislocation/stacking fault arrays and the grain refinement due to presence of the Epsilon-hcp martensite. DTIC

ION DOPED QUANTUM WELL LASERS Final Report, 15 Aug. 1992 - 14 Feb. 1993

Anton C. Greenwald Apr. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-92-C-0060)
(AD-A267198; AFOSR-93-0497TR) Avail: CASI HC A03

Synthesis of erbium-doped light-emitting structures will make it possible to fabricate electrically excited ionic lasers whose output frequency is independent of temperature. The emission wavelength is determined by the ionic properties of the dopant rather than by the band structure of the semiconductor. Optical pumping efficiency would be high, as would the electrical pumping efficiency of the semiconductor. Spire's approach to fabrication of the required structure is metalorganic chemical vapor deposition (MOCVD). In this research project, Spire synthesized and tested different metalorganic chemical sources for erbium. An amide compound, trimethyldisilylamino erbium, was found superior to the cyclopentadienyls as it reduced carbon contamination in the final film, without adding nitrogen or silicon contaminants. DTIC

LASER WITH OPTICALLY DRIVEN Q-SWITCH Patent Application

Hamid Hemmati, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 15 Jul. 1993 12 p
(Contract NAS7-918)
(NASA-Case-NPO-18470-1-CU; NAS 1.71:NPO-18470-1-CU;
US-Patent-Appl-SN-094332) Avail: CASI HC A03/MF A01

An optically driven interactive Q-switch, i.e., a Q-switch that responds to a short pulse of light, for example, from external light-emitting diodes (LEDs) or diode lasers, is provided for producing an output laser pulse from electronic energy stored in a laser medium. Q-switching is thus achieved

on demand by electrically pulsing the light source to produce a pulse of light directed onto a Q-switch medium in the laser cavity. Electronic control of the light pulse from the external source will thus provide not only efficient Q-switching frequency but also independent control of output laser pulse width with a fast rise time for each output laser pulse. NASA

N94-15942*# National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.

REDUCTION OF PARASITIC LASING Patent Application

Mark E. Storm, inventor (to NASA) (STX Corp., Hampton, VA.) 11 Aug. 1993 24 p

(NASA-Case-LAR-14645-1-SB; NAS 1.71:LAR-14645-1-SB; US-Patent-Appl-SN-105528) Avail: CASI HC A03/MF A01

A technique was developed which carefully retro-reflects precisely controlled amounts of light back into a laser system thereby intentionally forcing the laser system components to oscillate in a new resonator called the parasitic oscillator. The parasitic oscillator uses the laser system to provide the gain and an external mirror is used to provide the output coupling of the new resonator. Any change of gain or loss inside the new resonator will directly change the lasing threshold of the parasitic oscillator. This change in threshold can be experimentally measured as a change in the absolute value of reflectivity, provided by the external mirror, necessary to achieve lasing in the parasitic oscillator. Discrepancies between experimental data and a parasitic oscillator model are direct evidence of optical misalignment or component performance problems. Any changes in the optical system can instantly be measured as a change in threshold for the parasitic oscillator. This technique also enables aligning the system for maximum parasitic suppression with the system fully operational. NASA

FULL-WAVE SIMULATION OF THE THUMBTACK LASER

R. J. Hawkins, N. K. Madsen, J. S. Kallman, M. D. Feit, C. C. Shang, B. W. Shore, and J. F. DeFord Nov. 1992 5 p Presented at the Optical Society of America Integrated Photonics Research Topical Meeting, Palm Springs, CA, 22-25 Mar. 1993

(Contract W-7405-eng-48)

(DE93-015110; UCRL-JC-112217; CONF-930332-1) Avail: CASI HC A01/MF A01

The whispering-gallery mode microdisk--or thumbtack--laser is a novel, strongly confining, microstructure with 'potential for the integrability and low-power operation required for large-scale photonic integration.' It is a thin dielectric (n approximately 3.5) cylinder--or disk--on top of a rhomboid post. Analysis of the optical modes of this structure have, to date, consisted of scaling arguments drawn from the theory of whispering-gallery spheres. While this analysis has proved useful in understanding the basic aspects of the operation of this laser, it is limited. The authors have undertaken a complete electromagnetic analysis of the thumbtack laser using 2-D, 2.5-D, and 3-D Finite-Difference Time-Domain (FDTD) codes which range in complexity from 2-D studies of the mode structure of the disk to a geometrically complete 3-D analysis of the radiation emitted from the laser. The goal of this project is to predict changes in the optical behavior that accompany structural changes in and about the laser described elsewhere in these proceedings and to guide optimized device design. DOE

THE COOLING OF CONFINED IONS DRIVEN BY LASER BEAMS

L. G. Reyna and J. R. Sobehart 1993 13 p Presented at the New Synthesis Workshop for the Fluctuations and Order, Los Alamos, NM, 9-12 Sep. 1993

(Contract W-7405-eng-36)

(DE93-016612; LA-UR-93-2155; CONF-9309185-1) Avail: CASI HC A03/MF A01

We analyzed the dynamics of confined ions driven by a quantized radiation field. The ions can absorb photons from an incident laser beam and relax back to the ground state by either induced emissions or spontaneous emissions. Here we assume that the absorption of photons is immediately followed by spontaneous emissions, resulting in single-level ions perturbed by the exchange of momentum with the radiation field. The probability distribution of the ions is calculated using singular expansions in the low noise asymptotic limit. The present calculations reproduce the quantum results in the limit of heavy particles in static traps, and the classical results of ions in radio-frequency confining wells. DOE

SPATIAL AND FREQUENCY DIVERSITY IN LIDAR SYSTEMS Final Technical Report

John F. Ward 15 Jun. 1993 6 p

(Contract N00014-89-J-3213)

(AD-A266192) Avail: CASI HC A02/MF A01

The research is concerned with the signal to noise ratio of LIDAR signals. LIDAR is a remote sensing technique using light to gather information on molecular concentrations, wind velocities, and temperatures in the atmosphere on a temporally and spatially resolved basis. Our interest is in the statistical optics of the detection process rather than the data that might be collected in the ambient atmosphere, and our experiments, therefore, are carried out in the laboratory. The laboratory experiments are concerned with the fluctuations in LIDAR measurements. LIDAR signals typically arise from the backscatter of laser radiation from aerosols, and the return signal at the detector plane is spatially distributed in a speckle pattern. The contrast ratio in the pattern is unity, hence, an estimate of the average intensity from the intensity measured over a single speckle-area yields a signal-to-noise ratio of unity. DTIC

N94-16450# Lawrence Livermore National Lab., CA.

DESIGN OF A FORMALDEHYDE PHOTODISSOCIATION PROCESS FOR CARBON AND OXYGEN ISOTOPE SEPARATION

R. C. Stern and K. F. Scheibner 20 Jan. 1993 10 p Presented at the OE/LASE 1993 International Society for Optical Engineering Conference, Los Angeles, CA, 16-23 Jan. 1993

(Contract W-7405-eng-48)

(DE93-016435; UCRL-JC-110875; CONF-930159-40) Avail: CASI HC A02/MF A01

The current shortage of O-18 has revived interest in using one step UV photodissociation of formaldehyde to enrich C-13, O-17, and O-18. The frequency doubled output of the copper laser pumped dye laser system currently in operation at LLNL can be used to drive this dissociation. The authors use a simple kinetics model and their experience with atomic vapor laser isotope separation (AVLIS) process design to examine the relative merits of different designs for a formaldehyde photodissociation process. Given values for the molecular photoabsorption cross section, partition function, spectroscopic selectivity, collisional exchange and quenching cross sections (all as parameters), they perform a partial optimization in the space of illuminated area, formaldehyde pressure in each stage, and formaldehyde residence time in each stage. They examine the effect of cascade design (heads and tails staging) on molecule and photon utilization for each of the three isotope separation missions and look in one case at the system's response to different ratios of laser to formaldehyde costs. Finally, they examine the relative cost of enrichment as a function of isotope and product assay. Emphasis is as much on the process design methodology, which is general, as on the specific application to formaldehyde. DOE

POROUS SILICON FOR PUMPING SOLID-STATE LASERS Technical Report, Jun. - Sep. 1992

S. D. Russell, W. B. Dubbelday, and R. L. Shimabukuro Mar. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A266293; NCCOSC/RDT/E-TD-2461) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Preliminary experiments were performed to investigate the feasibility of using silicon-based sources to pump solid-state lasers. Photoluminescent porous silicon and porous silicon-on-sapphire (SOS) have been fabricated using chemical, electrochemical, and photochemical techniques. An electrochemically fabricated porous silicon sample exhibited 5% quantum efficiency when pumped with 5 mW of 457.9 nm argon ion laser light with a peak emission wavelength of 720 nm. This is consistent with other reports that efficiencies between 1 and 10% have been observed. This room temperature performance exceeds the early development of light emission from 3-5 semiconductors and suggests that continued research and development of the emission mechanism and optimization of the fabrication process can produce, at the very least, functionally equivalent results in a less expensive material which is amenable to large-scale integration. Stavnes (Sverdrup Technology, Inc., Brook Park, OH.) Feb. 1993 23 p Presented at the First Annual Wireless Power Transmission Conference, San Antonio, TX, 23-25 Feb. 1993; sponsored by the Center for Space Power
(Contract NAS3-25266; RTOP 593-32-41)
(NASA-TM-106110; E-7760; NAS 1.15:106110) Avail: CASI HC A03/MF A01

Earth-based laser sites beaming laser power to space assets have shown benefits over competing power system concepts for specific missions. Missions analyzed in this report that show benefits of laser beam power are low Earth orbit (LEO) to geosynchronous Earth orbit (GEO) transfer, LEO to low lunar orbit (LLO) cargo missions, and lunar-base power. Both laser- and solar-powered orbit-transfer vehicles (OTV's) make a 'tug' concept viable, which substantially reduces cumulative initial mass to LEO in comparison to chemical propulsion concepts. Lunar cargo missions utilizing laser electric propulsion from Earth-orbit to LLO show substantial mass saving to LEO over chemical propulsion systems. Lunar-base power system options were compared on a landed-mass basis. Photovoltaics with regenerative fuel cells, reactor-based systems, and laser-based systems were sized to meet a generic lunar-base power profile. A laser-based system begins to show landed mass benefits over reactor-based systems when proposed production facilities on the Moon require power levels greater than approximately 300 kWe. Benefit/cost ratios of laser power systems for an OTV, both to GEO and LLO, and for a lunar base were calculated to be greater than 1. Author (revised)

In an external lasing dye sensor system, a stream of lasing dye free-flows across an open area inside a chamber. An air sample comprising chemical vapor contaminants is pumped or drawn into the chamber. A laser beam is introduced into the chamber intersecting the lasing dye. A chemical reaction between the contaminants and the lasing dye result in a change in the emission spectra of the lasing dye. The change in emission spectra is detected and thus provides an improved apparatus for detecting low concentrations of chemical vapors in an air sample. DTIC

DIGITAL LASER RANGE FINDER EMULATOR Patent
Vaughn P. McDowell, inventor (to Navy), Orgal T. Holland, inventor (to Navy), and Christina G. Wilkerson, inventor (to Navy) 25 May 1993 6 p Filed 6 Aug. 1992
(AD-D015811; US-Patent-5,214,483; US-Patent-Appl-SN-925217; US-Patent-Class-356-5) Avail: US Patent and Trademark Office

A digital laser range finder emulator receives N-bits of range-to-target data in a parallel format and generates N-bits of serial data representative of the range-to-target data and an external synchronization pulse whose presence is indicative of valid serial data. First and second clock pulses are generated such that the second clock pulse is delayed with respect to the first clock pulse. Control logic, responsive to the first clock pulse, generates validity logic while control logic, responsive to the second clock pulse, generates transmit logic. The parallel format range-to-target data is converted into the serial data in response to the first clock pulse. The serial data is then output in response to the transmit logic. A gate, responsive to the second clock pulse and the validity logic, generates the synchronization pulse when the second clock pulse and validity logic occupy a common logic state. DTIC

[CONTROLLING CHAOTIC BEHAVIOR IN CO2 AND OTHER LASERS] Progress Report No. 3, 16 May - 15 Jun. 1993
25 Jun. 1993 21 p
(Contract N00014-93-C-0051)
(AD-A266431) Avail: CASI HC A03/MF A01

Additional substantial experimental progress has been made, in the third month of the project, in setting up equipment and testing for producing chaotic behavior with a CO2 laser. The project goal is to synchronize and control chaos in CO2 and other lasers, and thereby increase the power in ensembles of coupled laser sources. Numerous investigations into the chaos regime have been made, a second CO2 laser has been brought on stream, and work is progressing in the fourth month toward coupling the two lasers and control of the first laser. It is also intended to submit at least two papers to the Second Experimental Chaos Conference which is supported by the Office of Naval Research. Abstracts to those two papers are attached. Last month's report discussed the experimental investigation of nonlinear dynamics of CO2 lasers which involved a new technique of inducing chaos. In this new technique, an acoustically modulated feedback of the laser light was used and led to chaotic dynamics at a very low modulation frequency of 375 Hz. Since then, new results have been obtained by an Electro-Optical Modulation (EOM) technique. In the new setup, the electro-optical modulator is placed in an external cavity outside the laser. DTIC

PULSED LASER DEPOSITION OF METASTABLE Ca(1-x)Sr(x)CuO2 THIN FILMS
D. P. Norton, B. C. Chakoumakos, J. D. Budai, and D. H. Lowndes 1993 7 p Presented at the 2nd International Conference on Laser Ablation: Mechanisms and Applications, Knoxville, TN, 19-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015804; CONF-9304144-6) Avail: CASI HC A02/MF A01

One of the more interesting copper oxide materials is the tetragonal phase of Ca(1-x)Sr(x)CuO2, as it can be viewed as the parent structure of all of the high (Tc) superconducting cuprates. Although simple in structure, this copper oxide is metastable, requiring high pressures and temperatures for bulk synthesis. However, recent efforts have shown that formation of this phase can be achieved as an epitaxial thin film at low oxygen pressures (1-200 mTorr) and temperatures (450-700C) by pulsed laser deposition. We will discuss the growth of Ca(1-x)Sr(x)CuO2 by pulsed laser deposition, and the effects of various growth conditions on the transport and structural properties of these films. In particular, we will show that conductivity in this material can be significantly improved at the Sr-rich end of the solid solution. In addition, we discuss the effect of alkaline-earth (Sr, Ca) vacancies on transport properties of these thin films. DOE

ABLATION, SURFACE ACTIVATION, AND ELECTROLESS METALLIZATION OF INSULATING MATERIALS BY PULSED EXCIMER LASER IRRADIATION
D. H. Lowndes, M. J. Godbole, G. E. Jellison, Jr., and A. J. Pedraza 1993 9 p Presented at the 2nd International Conference on Laser Ablation: Mechanisms and Applications, Knoxville, TN, 19-22 Apr. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015808; CONF-9304144-5) Avail: CASI HC A02/MF A01

Pulsed-laser irradiation of wide bandgap ceramic substrates, using photons with sub-bandgap energies, activates the ceramic surface for subsequent electroless copper deposition. The copper deposit is confined within the irradiated region when the substrate is subsequently immersed in an electroless copper bath. However, a high laser fluence (typically several j/sq cm) and repeated laser shots are needed to obtain uniform copper coverage by this direct-irradiation process. In contrast, by first applying an evaporated SiO(x) thin film (with x approximately = 1), laser ablation at quite low energy density (approximately = 0.5 J/sq cm) results in re-deposition on the ceramic substrate of material that is catalytic for subsequent electroless copper deposition. Experiments indicate that the re-deposited material is on silicon, on which copper nucleates. Using an SiO(x) film on a laser-transparent substrate, quite fine (approximately 12 microns) copper lines can be formed at the boundary of the region that is laser-etched in SiO(x). Using SiO(x) with an absorbing (polycrystalline) ceramic substrate, more-or-less uniform activation and subsequent copper deposition are obtained. In the later case, interactions with the ceramic substrate also may be important for uniform deposition. DOE

LASER RANGING DATA ANALYSIS Final Report, 1987 - 1992 and Annual Report, 1991-1992
1992 4 p
(Grant NAG5-1021)
(NASA-CR-193547; NAS 1.26:193547) Avail: CASI HC A01/MF A01

Center for Space Research efforts have focused on the near real-time analysis of Lageos laser ranging data and on the production of predictive ephemerides. The data are analyzed in terms of range bias, time bias, and internal precision, and estimates for the Earth orientation parameters X(sub p), Y(sub p) and UT1 are obtained. The results of these analyses are reported in a variety of formats. In addition several additional stations began sending not only quick-look observations but also normal points created on-site with new software. These normal points are transmitted in a new standard format different from either current quick-look or MERIT-II full-rate formats. Thus new preprocessing software was written and successfully tested on these data. Inspection of the Bendix produced Lageos full-rate normal points continued, with detailed analyses and filtering of all 1991 A and B release normal points for Lageos through the beginning of 1992. A summary of the combined full-rate and quick-look normal point data set created for 1991 is provided. New long-term ephemerides for Lageos satellite, as well as for Etalon-1 and Etalon-2 (the so-called high satellites used for laser ranging) were produced and distributed to the network stations in cooperation with the Crustal Dynamics Project and Eurolas. These predictions are used by essentially every laser ranging site obtaining regular returns from any of these three satellites.

LASER WELD REPAIR OF TANTALUM SHEET
J. J. Oldani and C. N. Westrich Dec. 1992 9 p Presented at the 1992 International Conference on Lasers, Houston, TX, 7-11 Dec. 1992
(Contract W-7405-eng-48)
(DE93-016417; UCRL-JC-110669; CONF-921256-4) Avail: CASI HC A02/MF A01

Tantalum sheets which are used in radiographic film cassettes for high explosives studies, were repaired using Nd:YAG laser welding. The tantalum sheets can receive various levels of indentations and/or scratches which can leave radiographic indications during use in subsequent studies. Laser welding using a Raytheon 400 watt Nd:YAG laser and a 0.010 inch diameter tantalum filler wire with argon cover gas was used to fill in these false indications. A successful weld repair is required to give no radiographic indications--neither high nor low density readings. DOE

PULSED LASER KINETIC STUDIES OF LIQUIDS UNDER HIGH PRESSURE
E. M. Eyring 21 Jun. 1993 13 p
(Contract DE-FG02-84ER-13227)
(DE93-017826; DOE/ER-13227/7) Avail: CASI HC A03/MF A01

Experiments have been developed for measuring the rates of chemical reactions liquids and in supercritical CO2. A pulsed (Q-switch) Nd:YAG laser at 355 nm was the pump beam for laser flash photolysis studies of molybdenum and tungsten hexacarbonyls undergoing ligand displacement reactions by bidentate chelating agents such as 2,2'-bipyridine in toluene. Experiments were carried out at 0.1 to 150 MPa. In the case of molybdenum complexes, the reaction mechanism for thermal ring closure is found from activation volumes to change from associative interchange to dissociative interchange as substituents on the 2,2'-bipyridine ligands become bulkier. In a similar study of more rigid, substituted phenanthroline bidentate ligands it was found that substituent bulkiness had little effect on the thermal ring closure mechanism. Similar high pressure flash photolysis experiments with tungsten hexacarbonyl have also been completed. The concentration dependence of the fluorescence and nonradiative decay quantum yields for cresyl violet in several solvents has been reported as well as stability constants for the complexation of lithium ion by four different crown ethers dissolved in a room temperature molten salt. PULSED HYDROGEN FLUORIDE OVERTONE CHEMICAL LASER STUDIES Final Report, 1 Nov. 1990 - 31 Jan. 1992
W. R. Warren, Jr. and Leo E. Schneider 1 Feb. 1993 80 p
(Contract F49620-90-C-0008)
(AD-A267597; PAR-TM-93-103; AFOSR-93-103TR) Avail: CASI HC A05/MF A01

An experimental study of HF chemical lasers operating on overtone transitions, OT's, in a photolytically initiated, pulsed laser facility was conducted. The primary objective was to obtain comparisons of the specific energy performance of pulsed HF, chain reaction driven, chemical laser resonators when operating only on fundamental transitions, delta V = 1, and only on first overtone transitions, delta V = 2. The initial efforts were the buildup of the experimental test facility with which excellent performance as an FT HF laser was demonstrated. However, attempts to produce OT lasing using lambda-variable reflectivity mirror coatings (to promote and suppress, simultaneously, the OT and FT mechanisms) were only marginally successful, even though major facility modifications were made to reduce cavity losses, suppress FT superradiance (ASE), suppress parasitic modes, and increase pulse duration. Finally, CW OT lasing was demonstrated using the OT optical components in a combustion driven, blowdown test facility. A specific energy level, sigma = 266 w/gm/sec, was inferred from the measurements. DTIC

BIBLIOGRAPHY OF SHORT WAVELENGTH CHEMICAL LASER RESEARCH Technical Report
Glen P. Perram May 1993 64 p
(AD-A267619; AFIT/EN/TR/93-03) Avail: CASI HC A04/MF A01

High power short wavelength chemical laser (SWCL) systems offer great advantages for strategic and tactical military applications, including both weapons and imaging missions. The promise of very high brightness, high mass efficiency, and wavelength agility has justified a modest basic research program for more than a decade. Significant progress towards the demonstration of a visible chemical laser has been made during the past few years. Highly efficient methods of chemically producing metastable electronic states at concentrations exceeding 3 x 10(exp 16) molecules/cu cm have been developed. Energy transfer from these metastables to suitable lasant species has been used to demonstrate gain in the visible. Chemically generated gain of 0.029 %/cm on the (A-X) electronic transition in bismuth fluoride has been demonstrated using pulsed thermolysis of fluorine azide and trimethyl bismuth mixtures. Recently, a table-top shock facility has been used to achieve unsaturated lasing in the same system. During the past ten years, over 400 articles and reports have resulted from this

research program. This bibliography summarizes this Department of Defense sponsored research on short wavelength chemical lasers since 1980. DTIC

SODIUM-MERCURY EXCIMER LASER, PHASE 1 Final Report, Jun. - Dec. 1992
Malcolm W. McGeoch Dec. 1992 42 p
(Contract DASG60-92-C-0140)
(AD-A267726; PLEX-003) Avail: CASI HC A03/MF A01

This Phase 1 work addresses the technology required to test the sodium-mercury excimer laser concept. Calculations of the optimum laser excitation conditions show that a gain of 2.8% /cm should be achievable in the 1.2 micron region for a specific discharge power input of 20kW/cu cm. At the lower power input of 2kW/cu cm the projected gain is 1.5%/cu cm. The calculations consider the electron energy distribution function and collisional dissociation of NaHg(A) state molecules. Ultraviolet pre-ionization was shown to be a viable route to the attainment of high power discharges in this system. An experimental test of 600 deg C cell technology was performed, in which windows, lead-throughs and a close-out valve were cycled repeatedly to that temperature. DTIC

HAZARD CALCULATIONS OF DIFFUSE REFLECTED LASER RADIATION FOR THE SELENE PROGRAM
Gilda A. Miner and Phillip D. Babb (Bionetics Corp., Hampton, VA.) Washington Oct. 1993 8 p
(RTOP 506-41-41-01)
(NASA-TM-4520; L-17008; NAS 1.15:4520) Avail: CASI HC A02/MF A01

The hazards from diffuse laser light reflections off water clouds, ice clouds, and fog and from possible specular reflections off ice clouds were assessed with the American National Standards (ANSI Z136.1-1986) for the free-electron-laser parameters under consideration for the Segmented Efficient Laser Emission for Non-Nuclear Electricity (SELENE) Program. Diffuse laser reflection hazards exist for water cloud surfaces less than 722 m in altitude and ice cloud surfaces less than 850 m in altitude. Specular reflections from ice crystals in cirrus clouds are not probable; however, any specular reflection is a hazard to ground observers. The hazard to the laser operators and any ground observers during heavy fog conditions is of such significant magnitude that the laser should not be operated in fog. Author

EXPERIMENTAL STUDIES ON A GAS DYNAMIC LASER WITH NARROW THROAT AND HIGH AREA-RATIO GRID NOZZLES
20 Jul. 1993 14 p Transl. into ENGLISH from unidentified Chinese language document p 496-499
(AD-A267818; FASTC-ID(RS)T-0868-91) Avail: CASI HC A03/MF A01

This paper describes a combustion-driven CO2 gas dynamic laser (GDL) with a throat height of 0.3mm and a grid nozzle with an area-ratio of 30 and presents some experimental results. The behavior of the flow and the location of shock waves in the optical cavity were observed. The variation in small-signal gain G(sub 0) with CO2 or H2O contents were measured and compared with the experimental data from a similar set-up with a nozzle throat height of 0.8mm and an area-ratio of 17. Some of the advantages are obvious for the narrower throat height and higher area-ratio GDL: the G(sub 0) can be increased by a factor of 50%; and the H2O contents may be increased from 1% to 5%. BASIC STUDIES OF THE LIQUID STATE OF MATTER: ELECTRICAL PROPERTIES AND LASER INTERACTIONS Final Report
L. G. Christophorou and H. Faidas Jul. 1993 156 p
(Contracts N00014-89-J-1990; N00014-92-3-1606)
(AD-A268311) Avail: CASI HC A08/MF A02

This research involves basic studies of the electrical properties of the liquid state of matter. Given the intrinsic difficulties associated with physical studies of liquids (liquids lack the order of the crystal and the large inter-particle distances of the gas) we set out to develop new experimental techniques for and new approaches to the study of the electrical properties of liquids. The stated goals of this research were: (1) To establish a fundamental understanding of key basic processes and phenomena which determine the electrical properties of fluids; and (2) To use the new knowledge provided by the basic studies to benefit technological applications, especially in the areas of electrical breakdown of liquids, radiation detectors, pulsed power switches, and laser interactions in liquids. To meet these two goals, we emphasized studies in the following areas: (1) Electron production via ionization and injection in nonpolar liquids and dense gases; (2) Electron and ion transport in pure liquids and liquid mixtures; (3) Electron attachment and photodetachment in liquids; (4) Electron energetics in and mechanisms of the above processes; (5) Electrical breakdown and partial discharge in pure liquids and mixtures at high electric fields; (6) Technical aspects of liquids for advanced radiation detectors and pulsed power switches; and (7) Further development of liquid-filled flashlamp-operated pulsed power switch. Laser-plasma interaction studies and experiments related to laser driven

shocks as well as laser induced inertially confined thermonuclear fusion have resulted in an ever increasing demand for high brightness lasers capable of producing nanosecond pulse with energy of hundreds of kilo joules. High power Nd-glass laser chains with a master oscillator followed by a number of amplifier stages made up of rods, disks, slabs etc. are in operation in many leading laboratories in the world. This report describes the design, development and characterisation studies of a large aperture Nd:glass laser amplifier which is to be incorporated on line with the existing 40 J, 5 ns high power laser chain built for laser-plasma interaction and laser driven shock wave studies in the Laser and Plasma Technology Division. The development work described in this report discusses the design based on optimum material selection, optimisation of various sub components, ease of maintenance and smooth operation. The necessary operational electronics has also been described. The characterization studies mainly include measurement of spatial gain uniformity, thermally induced depolarization effects, and thermal relaxation studies. DOE

The United States Department of Energy (DOE) is facing a large task in characterizing and remediating the contents of hazardous waste inside storage tanks. The characterization process of these tanks is a key step to the remediation process. Due to the hazardous materials inside the waste tanks, all of the work must be done remotely utilizing robotic systems. The Laser Range Finder (LRF) is a single point sensor used to remotely collect range and intensity data. The LRF sensor data is used to reconstruct the tank surface environment based on multiple LRF scans. This reconstructed surface definition can be used by a robotic controller to perform obstacle avoidance with items in the tank. The Pacific Northwest Laboratory (PNL) has used Advanced Visualization System (AVS) to prototype the filtering, transformation, and reconstructing process. AVS software modules have been written to address LRF filtering on both the range and intensity images. A coordinate transformation module was constructed to convert the raw LRF data into a Cartesian coordinate reference frame. The results of filtering and transforms are integrated into a master map of the tank using an octree database. Master octrees are traversed and made into AVS geometry to visualize the tank interior. The graphical display of the tank interior can be used for robotic path planning and monitoring waste removal progress. DOE

BIBLIOGRAPHY ON SNOW AND ICE FRICTION
Samuel C. Colbeck May 1993 22 p
(DA Proj. 4A7-62784-AT-42)
(AD-A266868; CRREL-SR-93-6) Avail: CASI HC A03/MF A01

This is a bibliography compiled for use by anyone interested in friction on snow or ice surfaces. The items are separated into snow and ice categories because the physical processes and the problems on these two surfaces are somewhat different. There is some repetition between the lists because some references are appropriate for both subjects. The references were selected because they were of direct interest to the subject of friction and not just because knowledge of friction was important in the study. That is, the references selected provide information about friction and do not just use such information. DTIC

REAL-TIME IMPLEMENTATION OF NEURAL NETWORK LEARNING CONTROL OF A FLEXIBLE SPACE MANIPULATOR
R. T. Newton and Yangsheng Xu Aug. 1992 29 p
(AD-A266962; CMU-RI-TR-92-11) Avail: CASI HC A03/MF A01

This paper discusses a neural network approach to on-line control learning and real-time implementation for a flexible space robot manipulator. We at first overview the system development of the Self-Mobile Space Manipulator (SM2) and discuss the motivations of our research. Then, we propose a neural network to learn control by updating feedforward dynamics based on feedback control input. We address in great detail the implementation issues associated with on-line training strategies and present a simple stochastic training scheme. A new recurrent neural network architecture is proposed, and the performance is greatly improved in comparison to the standard neural network. By using the proposed learning scheme, manipulator trajectory error is reduced by 85 percent. At last, we discussed the implementation of the proposed scheme in teleoperated control. The approach possesses a high degree of generality and adaptability in various applications and will be a valuable method in learning control for robots working in unconstructed environments. DTIC

DETERMINATION OF GTA WELDING EFFICIENCIES M.S. Thesis

Candonino P. Franche Mar. 1993 24 p

(AD-A267163) Avail: CASI HC A03/MF A01

A method is developed for estimating welding efficiencies for moving arc GTAW processes. Under quasi-conditions, the net heat transfer rate from the weld pool to the work piece is estimated from a 3-D numerical heat transfer conduction model. The dimensions of the weld pool used in the computational model are obtained experimentally using a laser vision system and by metallurgical examination. The welding efficiency is then calculated by dividing the net heat transfer rate by the total power input during the experiments. Efficiencies are measured for a range of power inputs and torch speeds and then compared with those available in the literature. DTIC

EXPLOSIVE BOILING AT VERY LOW HEAT FLUXES: A MICROGRAVITY PHENOMENON

M. M. Hasan, C. S. Lin (Analex Corp., Brook Park, OH.), R. H. Knoll, and M. D. Bentz (Boeing Defense and Space Group, Seattle, WA.) Nov. 1993 9 p Prepared for presentation at the ASME Winter Annual Meeting, New Orleans, LA, 28 Nov. - 3 Dec. 1993; sponsored by ASME (RTOP 506-42-73)

(NASA-TM-106325; E-8078; NAS 1.15:106325) Avail: CASI HC A02/MF A01

The paper presents experimental observations of explosive boiling from a large (relative to bubble sizes) flat heating surface at very low heat fluxes in microgravity. The explosive boiling is characterized as either a rapid growth of vapor mass over the entire heating surface due to the flashing of superheated liquid or a violent boiling spread following the appearance of single bubbles on the heating surface. Pool boiling data with saturated Freon 113 was obtained in the microgravity environment of the space shuttle. The unique features of the experimental results are the sustainability of high liquid superheat for long periods and the occurrence of explosive boiling at low heat fluxes (0.2 to 1.2 kW/sq m). For a heat flux of 1.0 kW/sq m a wall superheat of 17.9 degrees C was attained in ten minutes of heating. This was followed by an explosive boiling accompanied with a pressure spike and a violent bulk liquid motion. However, at this heat flux the vapor blanketing the heating surface could not be sustained. Stable nucleate boiling continued following the explosive boiling. Author (revised)

SPLINE SCREW PAYLOAD FASTENING SYSTEM Patent Application

John M. Vranish, inventor (to NASA) 21 Sep. 1992 45 p

(NASA-Case-GSC-13454-1; NAS 1.71:GSC-13454-1; US-Patent-Appl-SN-947612) Avail: CASI HC A03/MF A01

A system for coupling an orbital replacement unit (ORU) to a space station structure via the actions of a robot and/or astronaut is described. This system provides mechanical and electrical connections both between the ORU and the space station structure and between the ORU and the ORU and the robot/astronaut hand tool. Alignment and timing features ensure safe, sure handling and precision coupling. This includes a first female type spline connector selectively located on the space station structure, a male type spline connector positioned on the orbital replacement unit so as to mate with and connect to the first female type spline connector, and a second female type spline connector located on the orbital replacement unit. A compliant drive rod interconnects the second female type spline connector and the male type spline connector. A robotic special end effector is used for mating with and driving the second female type spline connector. Also included are alignment tabs exteriorally located on the orbital replacement unit for berthing with the space station structure. The first and second female type spline connectors each include a threaded bolt member having a captured nut member located thereon which can translate up and down the bolt but are constrained from rotation thereabout, the nut member having a mounting surface with at least one first type electrical connector located on the mounting surface for translating with the nut member. At least one complementary second type electrical connector on the orbital replacement unit mates with at least one first type electrical connector on the mounting surface of the nut member. When the driver on the robotic end effector mates with the second female type spline connector and rotates, the male type spline connector and the first female type spline connector lock together, the driver and the second female type spline connector lock together, and the nut members translate up the threaded bolt members carrying the first type electrical connector up to the complementary second type connector for interconnection therewith. NASA

AN IMPROVED PATCH FOR RADIATIVE COOLERS Patent Application

Vincent T. Bly, inventor (to NASA) 25 Jan. 1993 15 p

(NASA-Case-GSC-13503-1; NAS 1.71:GSC-13503-1; US-Patent-Appl-SN-008427) Avail: CASI HC A03/MF A01

A unique structure for constructing the emissive patch of a spaceborne

radiative cooler is shown. The structure has very high emissivity for all angles up to a designed-in maximum angle and near zero emissivity for greater angles. The structure also allows the use of high emissivity, nonconducting paints while fully complying with the NASA Electrostatic Discharge Susceptibility requirements for spacecraft. To accomplish these tasks, two previous disadvantages of prior art methods are addressed; eliminating background thermal radiation sources and problems concerning the high emissivity paints used in association with the black body radiator. A reflector consisting of an array of parabolic concentrators is separated from a black body element by an electrically conductive spacer. The concentrators serve to limit the field of view while the conductive spacer eliminates the need to use a conductive paint on the emissive element.

WELDING NOZZLE POSITION MANIPULATOR Patent Application
Jeffrey L. Gilbert, inventor (to NASA) (Rockwell International Corp., Canoga Park, CA.) and David A. Gutow, inventor (to NASA) (Rockwell International Corp., Canoga Park, CA.) 31 Aug. 1993 16 p
(NASA-Case-MFS-29837-1; NAS 1.71:MFS-29837-1;
US-Patent-Appl-SN-114043) Avail: CASI HC A03/MF A01

The present invention is directed to a welding nozzle position manipulator. The manipulator consists of an angle support to which the remaining components of the device are attached either directly or indirectly. A pair of pivotal connections attach a weld nozzle holding link to the angle support and provide a two axis freedom of movement of the holding link with respect to the support angle. The manipulator is actuated by a pair of adjusting screws angularly mounted to the angle support. These screws contact a pair of tapered friction surfaces formed on the upper portion of the welding nozzle holding link. A spring positioned between the upper portions of the support angle and the holding link provides a constant bias engagement between the friction surfaces of the holding link and the adjustment screws, so as to firmly hold the link in position and to eliminate any free play in the adjustment mechanism. The angular relationships between the adjustment screws, the angle support and the tapered friction surfaces of the weld nozzle holding link provide a geometric arrangement which permits precision adjustment of the holding link with respect to the angle support and also provides a solid holding link mount which is resistant to movement from outside forces.

MECHANICAL ENERGY ABSORBER Patent Application
Clarence J. Wesselski, inventor (to NASA) (Lockheed Engineering and Sciences Co., Houston, TX.) 29 Jul. 1993 19 p
(NASA-Case-MSC-22111-1; NAS 1.71:MSC-22111-1;
US-Patent-Appl-SN-098911) Avail: CASI HC A03/MF A01

An energy absorbing system for controlling the force where a moving object engages a stationary stop and where the system utilized telescopic tubular members, energy absorbing diaphragm elements, force regulating disc springs, and a return spring to return the telescoping member to its start position after stroking is presented. The energy absorbing system has frusto-conical diaphragm elements frictionally engaging the shaft and are opposed by a force regulating set of disc springs. In principle, this force feedback mechanism serves to keep the stroking load at a reasonable level even if the friction coefficient increases greatly. This force feedback device also serves to desensitize the singular and combined effects of manufacturing tolerances, sliding surface wear, temperature changes, dynamic effects, and lubricity.

US-Patent-Class-415-90) Avail: US Patent and Trademark Office

The invention is directed to a device for pumping electro-rheological fluids comprising a casing that defines an inner rotor chamber having a central inlet opening and a peripheral discharge opening. Rotatably disposed within said chamber is a rotor for imparting energy to the pumped electro-rheological fluid comprising of a plurality of non-conducting coaxial substantially parallel spaced disks. On one face of each disk are embedded one or more electrodes and on the opposing face of each disk are attached one or more conductive surfaces. By selectively applying an electric charge to the embedded electrodes, an electric field is produced between the electrodes and the conducting surfaces of adjacent disks. As a result, the viscosity of the electro-rheological fluid exposed to the applied electric field is increased thereby producing electro-rheological fluid vanes between adjacent disks. When the rotor is placed in rotation and a voltage is applied to the embedded electrodes, the electro-rheological fluid that is not exposed to the applied electric field, it is accelerated from the center of the rotor towards the outer periphery by the combined action of the electro-rheological fluid vanes and the friction force acting between the fluid and the rotating disks.

TILT MECHANISM Patent
Kenneth W. Stark, inventor (to Navy) 5 Jan. 1993 9 p Filed 3 Apr. 1991
(AD-D015780; US-Patent-5,177,644; US-Patent-Appl-SN-679904;
US-Patent-Class-359-896) Avail: US Patent and Trademark Office

A tilt mechanism includes a rigid base member, a first tilt plate pivotally mounted on the base member, and a second tilt plate pivotally mounted on the first tilt plate. The first and second tilt plates are pivoted via actuating mechanisms which include stepper motors, harmonic drives, and precision nuts which translate the rotational output of the harmonic drives to pivotal motion of the tilt plates. All of the movable components of the mechanism are mounted to one another via flexural pivots which allow at least limited rotation in one direction but which prevent movement in all other directions.

DYNAMICS, STABILITY, AND CONTROL OF MAGLEV SYSTEMS
Y. Cai, S. S. Chen, D. M. Rote, and H. T. Coffey 1993 7 p Presented at the 12th International Conference on Magnetically Levitated Systems

and Linear Drives, Argonne, IL, 19-21 May 1993
(Contract W-31-109-eng-38)
(DE93-015163; ANL/MCT/CP-79590; CONF-930550-5) Avail: CASI HC A02/MF A01

The dynamic response of maglev systems is important in several respects: Safety and ride quality, guideway design, and system costs. The dynamic response of vehicles is the key element in the determination of ride quality, and vehicle stability is one of the important elements relative to safety. To design a proper guideway that provides acceptable ride quality in the stable region, the vehicle dynamics must be understood. The trade-off between guideway smoothness and the levitation and control systems must be considered if maglev systems are to be economically feasible. This paper is a summary of our previous work on dynamics, stability, and control of maglev systems. First of all, the importance of dynamics of vehicle/guideway of maglev systems is discussed. Emphasis is placed on the modeling vehicle/guideway interactions of maglev systems with a multicar, or multiload vehicle traversing on a single or double-span flexible guideway. Coupled effects of vehicle/guideway interactions in wide range of vehicle speeds with various vehicle and guideway parameters for maglev systems are investigated. Secondly, the alternative control designs of maglev vehicle suspension systems are investigated in this study to achieve safe, stable operation and acceptable ride comfort requires some form of vehicle motion control. Active and semi-active control law designs are introduced into primary and secondary suspensions of maglev vehicles. Finally, this paper discusses the stability of maglev systems based on experimental data, scoping calculations, and simple mathematical models. Divergence and flutter are obtained for coupled vibration of a three-degree-of-freedom maglev vehicle on a guideway consisting of double L-shaped aluminum segments. The theory and analysis developed in this study provides basic stability characteristics and identifies future research needs for maglev systems. DOE

HIGH PRESSURE PUMP FOR ELECTRO-RHEOLOGICAL FLUIDS Patent
Mark E. Shiffler, inventor (to Navy) and Luke W. Loy, inventor (to Navy) 20 Jul. 1993 4 p Filed 30 Sep. 1992
(AD-D015888; US-Patent-5,226,837; US-Patent-Appl-SN-953338; US-Patent-Class-417-48) Avail: US Patent and Trademark Office

A high-pressure pump for electrorheological fluids in which the pump components operate with relatively large clearances and rely on the electrorheological fluid effect for sealing. Preferably, the electrorheological effect is induced in the fluid only in the region where a seal between relatively merging pump parts is required to generate a fluid pressure increase. DTIC

THREE AXIS FORCE OVERRIDE RATE CONTROL OF A PUMA 560 MANIPULATOR M.S. Thesis
Larry P. Ondrey Mar. 1993 126 p
(AD-A267313) Avail: CASI HC A07/MF A02

This paper discusses the implementation of unilateral force override of rate control of a PUMA 560 robot manipulator in three degrees of freedom. A control system is developed utilizing the necessary sensors, hardware, and software interface to enable one to operate the manipulator in rate control with unilateral force control override. A review of the theory behind such a controller is conducted and stability issues addressed. A comparison of experimental results with the theoretical results is conducted and a simple program is developed to simulate the manipulator's response. These simulation results are compared to the experimental data. DTIC

HIGH TEMPERATURE HYDRAULIC SEALS Final Report, Oct. 1987 - Nov. 1992
K. R. Williams May 1993 154 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-87-C-2710)
(AD-A268257; MDC-92K0395; WL-TR-93-2036) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This program investigated and evaluated high temperature hydraulic sealing technology, including seals, fluids, and actuator materials. Test limits for fluid pressure and temperature were 8000 psi and 700 F respectively. The original plan to investigate CTFE fluid at 350 F as well as other fluids at higher temperatures was reduced in scope to include only the higher temperature investigation. Seals were obtained from 11 manufacturers. Design requirements including materials, dimensions, clearances, and tolerances were established and test modules were constructed from the detail designs which were produced. Nine piston seals and one rod seal were tested at temperatures ranging from -65 to +600 F and pressures to 6000 psi. Fluid performance under these conditions was evaluated. Details of this activity and results of the effort are summarized in this report. DTIC

A MECHANICAL SYSTEM DAMPING MEASUREMENT TECHNIQUE USING A ONE-DEGREE-OF-FREEDOM (1DOF) CYLINDRICAL GAS BEARING Final Report, 13 Feb. - 30 Sep. 1992
C. L. Ratliff and E. J. Marquart Aug. 1993 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268402; AEDC-TR-93-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An experimental investigation was conducted in the Airflow Calibration Laboratory (ACL) to separate the total rolling moment of rigid and nonrigid mechanical systems into viscous damping and coulomb rolling-moment components. The test technique consisted of measuring roll rate decay of these rigid and nonrigid mechanical systems on a one-degree-of-freedom (1 DOF) cylindrical gas bearing. To better understand the 1 DOF bearing tare damping, a significant amount of information was collected about the operational characteristics of the 1DOF cylindrical gas bearing at certain test conditions. The 1DOF bearing characteristics and test technique are described in this report. The application of the test technique developed for this investigation could be beneficial for determining damping properties of other mechanical systems such as turbomachinery, space structures, gas/ball bearings, and high-damping-capacity materials. The primary measurement uncertainties for the present investigation were determined as follows: +/- 0.01 deg/sec for roll rate obtained with a one-spot tachometer ring, +/- 0.001 in.-lbf for viscous damping moment, or, in terms of energy dissipation, +/- 1 mW. The coulomb rolling-moment uncertainty could not be established because of its variable nature. DTIC

ATOMIC-SCALE FRICTION MEASUREMENTS USING FRICTION FORCE MICROSCOPY. PART 1: GENERAL PRINCIPLES AND NEW MEASUREMENT TECHNIQUES

Ju-Ai Ruan and Bharat Bhushan 11 Feb. 1993 49 p
(Contract N00014-93-1-0067)
(AD-A268391) Avail: CASI HC A03/MF A01

Friction force measurements using modified atomic force microscopy, called here Friction Force Microscopy (FFM), are becoming increasingly important in the understanding of fundamental mechanisms of friction, wear, and lubrication, and to study interfacial phenomenon in micro- and nanostructures used in magnetic storage systems and micro-electromechanical systems (MEMS). A review of existing designs of FFM's and methods of friction force measurements is presented. In terms of friction force measurements, there are important issues related to the basic operation and calibration of these instruments which have not been fully studied. A new method of measuring friction force using a commercial FFM and a calibration procedure for conversion of measured data to normal and friction forces are presented. Atomic-scale friction data of selected materials are presented and discussed in light of macro-friction measurements. DTIC

(Contract N00014-92-J-1608)
(AD-A268291) Avail: CASI HC A03/MF A01

This project was designed to provide new information on the effects of ion implantation on surface (adhesion) and subsurface (deformation) effects during unlubricated sliding of metals. The base materials are copper and iron, and the implanted species are also copper and iron. Thus, in some samples there should only be structural changes caused by implantation (e.g., Fe into Fe, Cu into Cu), while in others there will be composition changes as well (e.g., Cu into Fe, Fe into Cu). Copper and iron were chosen because of the considerable amount of literature available for comparison of results from testing of these metals. Also, their hardness values and deformation behavior are different, the OSU group has experience with both metals, and the phenomenon of selective transfer, extensively studied in the former USSR, usually involves both Cu and Fe. SOME SINGLE-PISTON CLOSED-CYCLE MACHINES AND PETER TAILER'S THERMAL LAG ENGINE
C. D. West 1993 8 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015983; CONF-930804-8) Avail: CASI HC A02/MF A01

Peter Tailer has devised, built, and operated a beautifully simple engine with a closed working gas cycle, external heating, and only a single piston. The aim of this paper is to cast some light on the possible modes of operation for his machine. The methods developed to analyze certain aspects of Stirling cycle engines, and especially the thermodynamic losses incurred in systems that are neither perfectly isothermal nor perfectly adiabatic, can be applied to Tailer's system. The results identify two idealized cycles fr such machines; relate those cycles to a single piston, ported cylinder machine proposed earlier; and offer a possible explanation for the success of the thermal lag engine. Mathematical techniques underlying computer aided inspection methods used for checking whether a manufactured part is within tolerance are addressed. Tolerance assessment is a key step in maintaining and improving quality in manufactured products. Means by which a class of design and tolerance specifications can be formulated in terms of parametrized curves and surfaces and parameter and form constraints are described. The tolerance assessment problem can then be addressed by optimization techniques. It is shown how many important tolerance assessment problems can be formulated as simple matching problems for which efficient solution algorithms can be developed. ESA

SYNCHRONOUS SAMPLING PHASE AND AMPLITUDE DETECTION METHOD AND APPARATUS Patent Application
Mark E. Froggatt, inventor (to NASA) 19 Aug. 1993 26 p
(NASA-Case-LAR-14725-1; NAS 1.71:LAR-14725-1;
US-Patent-Appl-SN-110255) Avail: CASI HC A03/MF A01

A synchronous sampling phase and amplitude detection method and apparatus is described. An oscillator generates a signal at a particular frequency and then a frequency dividing circuit divides this signal frequency by a factor of four. This divided signal is transmitted via a transducer through a material and received by the same or another transducer. The received signal is then digitized. The received signal is next sampled at four times its frequency based on a reference signal from the oscillator and then characterized as a phasor. The phase and amplitude of the received signal are then calculated via trigonometric relationship of at least two samples separated by 90 degrees. The remaining samples are employed to reduce the noise equivalent bandwidth. NASA

I'm very pleased to be here and to have this opportunity to discuss with you what I view as the current challenges in space science. Today, NASA finds itself at a major crossroads. We are in the process of moving from one era in our existence into another. As we continue to launch important science missions, we are simultaneously changing the way we do business, in a very fundamental way. We are again focusing on more frequent access to space through smaller, less costly missions. We are again focusing on NASA's role as a source of technological advancement within the U.S. economy. And we are returning to the leaner, more flexible approach to managing our projects. In short, NASA has embarked on a new journey, and a challenging journey it will be. Author

As previous speakers have said, profound changes are occurring in the world and the aerospace marketplace. It seems that everyone in the industry is struggling to adapt to the new environment and to survive. To meet this challenge, new ways of doing business are being adopted. Methods that enable products to be produced better, faster, and cheaper. One of the most powerful techniques is what we call Product Development Teams (PDT's). What others may call Design-Build Teams or Concurrent Engineering. At Boeing, we have found these team approaches to be a highly effective way of increasing quality while simultaneously reducing flow time and cost. We have also found that they have a very positive effect on employee morale. Because of our successes, we are making them the standard way of operating on every program we conduct. Today, I'd like to provide a short overview of how we're using teams at Boeing with special attention to subcontractor and customer involvement. I start by reviewing why change is needed. Up until a few short months ago, the phase out of ozone-layer-depleting, chlorinated solvents seemed like an event in our far distant future. Then, this past November, at the Copenhagen meeting of the Montreal Protocol

Working Group, the final phase out date for CFC-113 and 1,1,1 trichloroethane was accelerated to 1995. Then DuPont, one of the world's largest producers of CFC-113, announced that they would cease production in 1994. All of a sudden, this issue became a short-term crisis to react to, rather than a long term opportunity for continuous improvement. Now we are trying to react. If we pay attention to the obstacles we encounter along the way, perhaps we can learn from this crisis -- learn how to set ourselves up to avoid this type of environmental crisis management, when the next legislative shoe drops (as it certainly will). For those of us committed to careers in environmental management or corporate industrial management, this knowledge will be invaluable in the years ahead. Author (revised)

ALUMINUM-LITHIUM TECHNOLOGY c26

E. Powers and P. Hartley *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 4 p (For primary document see N94-16129 03-38)

(TABES Paper 93-601) Avail: CASI HC A01/MF A03

Advances in ingot casting technology have enabled aluminum manufacturers to produce commercial quantities of high quality aluminum-lithium material. While still being in the specialty metal price range (greater than $10/lb), the increased strength and modulus, along with decreased density, of aluminum-lithium alloys offer attractive performance and weight savings benefits. Martin Marietta has been involved in the development of aluminum-lithium alloys for use on cryogenic launch vehicles from laboratory to production quantities. Since the inception of the Weldalite family of alloys at the Martin Marietta Laboratories, Martin Marietta has focused developmental activities on the Weldalite alloys. Now, after seven years, Weldalite alloys are available in production quantities. As the marketplace becomes more weight/performance driven, the demand for light weight alternatives to conventional metals is increasing. This paper examines the technological advances made during the Weldalite development that have enabled the alloy to become an attractive alternative to conventional aluminum alloys. Author (revised)

THE MARSHALL AUTOMATED WELD SYSTEM (MAWS) c37

Carolyn K. Russell, Kirby G. Lawless, and A. C. Nunes *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)

(TABES Paper 93-602) Avail: CASI HC A02/MF A03

A fully automated welding system, which can operate totally independent of human intervention, is currently unavailable in the welding industry. Development of the Marshall Automated Weld System (MAWS) has been undertaken to fill this void. The system will enable application of statistical process control practices to assure weld quality prior to post weld nondestructive testing. The Variable Polarity Plasma Arc (VPPA) welding process has been baselined for MAWS because it has eliminated process related defects in the welding of the Space Shuttle External Tank. The few remaining weld defects occurring on the tank can be associated with human error. The system integrates multiple sensors (providing real time information on weld bead geometry, weld joint location, wirefeed entry, and inert gas quality) with a weld model (describing weld geometry in relation to critical parameters) and computer controlled VPPA weld equipment. This system is designed to provide real-time, closed-loop control of the weld as it is being made. Author

PLASMA ARC WELDING REPAIR OF SPACE FLIGHT HARDWARE c37

David S. Hoffman *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 5 p (For primary document see N94-16129 03-38)

(TABES Paper 93-603) Avail: CASI HC A01/MF A03

Repair and refurbishment of flight and test hardware can extend the useful life of very expensive components. A technique to weld repair the main combustion chamber of space shuttle main engines has been developed. The technique uses the plasma arc welding process and active cooling to seal cracks and pinholes in the hot-gas wall of the main combustion chamber liner. The liner hot-gas wall is made of NARloyZ, a copper alloy previously thought to be unweldable using conventional arc welding processes. The process must provide extensive heat input to melt the high conductivity NARloyZ while protecting the delicate structure of the surrounding material. The higher energy density of the plasma arc process provides the necessary heat input while active water cooling protects the surrounding structure. The welding process is precisely controlled using a computerized robotic welding system. Author

ADAPTIVE WELD CONTROL FOR HIGH-INTEGRITY WELDING APPLICATIONS c37

Bradley W. Powell *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)

(TABES Paper 93-604) Avail: CASI HC A02/MF A03

Adaptive, closed-loop weld control is necessary to maintain high-integrity, zero-defect welds. Conventional weld control techniques using weld parameter feedback control loops are sufficient to maintain set points, but fall short when confronted with unexpected variations in part/tooling temperature and mechanical structure, weldment material, arc skew angle, or calibration in weld parameter feedback measurement. Modern technology allows closed-loop control utilizing input from real-time weld monitoring sensors and inspection devices. Weld puddle parameters, bead profile parameters, and weld seam position are fed back into the weld control loop which adapts for the weld condition variations and drives them back to a desired state, thereby preventing weld defects or perturbations. Parameters such as arc position relative to the weld seam, puddle symmetry, arc length, weld width, and bead shape can be extracted from sensor imagery and used in closed-loop active weld control. All weld bead and puddle measurements are available for real-time display and statistical process control analysis, after which the data is archived to permanent storage or later retrieval and analysis. THERMAL SPRAY FORMING OF REFRACTORY SAMPLE AMPOULE CARTRIDGES FOR SINGLE CRYSTAL GROWTH SPACE FURNACES c76

Frank Zimmerman, Richard Poorman, Richard Holmes, Timothy McKechnie (Rockwell International Corp., Canoga Park, CA.), Phil Krotz (Rockwell International Corp., Canoga Park, CA.), and Yoon Liaw (Rockwell International Corp., Canoga Park, CA.) *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 5 p (For primary document see N94-16129 03-38)

(TABES Paper 93-605) Avail: CASI HC A01/MF A03

A thermal spray process is being used to build up refractory metals and ceramics into a containment cartridge for high temperature, single crystal semiconductor growth experiments. This process uses high energy plasma inside a low pressure (100-200 torr) inert environment to apply layers of material onto a removable mandrel. A variety of materials are being characterized and evaluated against a demanding set of requirements, including high service temperature (1700 C), oxidation resistance, and resistance to liquid metal attack. Techniques to spray form refractory metals (tungsten, molybdenum, niobium, tantalum) and ceramics (alumina, boron nitride) are being developed in the Plasma Spray Cell at Marshall Space Flight Center. These plasma spray formed materials have been evaluated for mechanical properties, density, microstructure, and resistance to liquid metal attack. Forming techniques and the resultant mechanical and metallurgical properties are presented. Author

MATERIALS, PROCESSES, AND ENVIRONMENTAL ENGINEERING NETWORK c82

Margo M. White *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 5 p (For primary document see N94-16129 03-38)

(TABES Paper 93-610) Avail: CASI HC A01/MF A03

The Materials, Processes, and Environmental Engineering Network (MPEEN) was developed as a central holding facility for materials testing

information generated by the Materials and Processes Laboratory. It contains information from other NASA centers and outside agencies, and also includes the NASA Environmental Information System (NEIS) and Failure Analysis Information System (FAIS) data. Environmental replacement materials information is a newly developed focus of MPEEN. This database is the NASA Environmental Information System, NEIS, which is accessible through MPEEN. Environmental concerns are addressed regarding materials identified by the NASA Operational Environment Team, NOET, to be hazardous to the environment. An environmental replacement technology database is contained within NEIS. Environmental concerns about materials are identified by NOET, and control or replacement strategies are formed. This database also contains the usage and performance characteristics of these hazardous materials. In addition to addressing environmental concerns, MPEEN contains one of the largest materials databases in the world. Over 600 users access this network on a daily basis. There is information available on failure analysis, metals and nonmetals testing, materials properties, standard and commercial parts, foreign alloy cross-reference, Long Duration Exposure Facility (LDEF) data, and Materials and Processes Selection List data.

NASA OPERATIONAL ENVIRONMENT TEAM (NOET): NASA'S KEY TO ENVIRONMENTAL TECHNOLOGY **c45**

Beth Cook *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 4 p (For primary document see N94-16129 03-38)

(TABES Paper 93-611) Avail: CASI HC A01/MF A03

NASA has stepped forward to face the environmental challenge to eliminate the use of Ozone-Layer Depleting Substances (OLDS) and to reduce our Hazardous Air Pollutants (HAP) by 50 percent in 1995. These requirements have been issued by the Clean Air Act, the Montreal Protocol, and various other legislative acts. A proactive group, the NASA Operational Environment Team or NOET, received its charter in April 1992 and was tasked with providing a network through which replacement activities and development experiences can be shared. This is a NASA-wide team which supports the research and development community by sharing information both in person and via a computerized network, assisting in specification and standard revisions, developing cleaner propulsion systems, and exploring environmentally-compliant alternatives to current processes. This project served to define an appropriate methodology for effective prioritization of technology efforts required to develop replacement technologies mandated by imposed and forecast legislation. The methodology used is a semi-quantative approach derived from quality function deployment techniques (QFD Matrix). This methodology aims to weight the full environmental, cost, safety, reliability, and programmatic implications of replacement technology development to allow appropriate identification of viable candidates and programmatic alternatives. The results will be implemented as a guideline for consideration for current NASA propulsion systems. Author

LIQUID HYDROGEN AND LIQUID OXYGEN FEEDLINE PASSIVE RECIRCULATION ANALYSIS **c34**

Kimberly Ann Holt, Nicole L. Cleary, Andrew J. Nichols, and Gretchen L. E. Perry *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 5 p (For primary document see N94-16129 03-38)

(TABES Paper 93-620) Avail: CASI HC A01/MF A03

The primary goal of the National Launch System (NLS) program was to design an operationally efficient, highly reliable vehicle with minimal recurring launch costs. To achieve this goal, trade studies of key main propulsion subsystems were performed to specify vehicle design requirements. These requirements include the use of passive recirculation to thermally condition the liquid hydrogen (LH2) and liquid oxygen (LO2) propellant feed systems and Space Transportation Main Engine (STME) fuel pumps. Rockwell International (RI) proposed a joint independent research and development (JIRAD) program with Marshall Space Flight Center (MSFC) to study the LH2 feed system passive recirculation concept. The testing was started in July 1992 and completed in November 1992. Vertical and sloped feedline designs were used. An engine simulator was attached at the bottom of the feedline. This simulator had strip heaters that were set to equal the corresponding heat input from different engines. A computer program is currently being used to analyze the passive recirculation concept in the LH2 vertical feedline tests. Four tests, where the heater setting is the independent variable, were chosen. While the JIRAD with RI was underway, General Dynamics Space Systems (GDSS) proposed a JIRAD with MSFC to explore passive recirculation in the LO2 feed system. Liquid nitrogen (LN2) is being used instead of LO2 for safety and economic concerns. To date, three sets of calibration tests have been completed on the sloped LN2 test article. The environmental heat was calculated from the calibration tests in which the strip heaters were turned off. During the LH2 testing, the environmental heat was assumed to be constant. Therefore, the total heat was equal to the environmental heat flux plus the heater input. However, the first two sets of LN2 calibration tests have shown that the environmental heat flux varies with heater input. A Systems Improved Numerical Differencing Analyzer and Fluid Integrator (SINDA/FLUINT) model is currently being built to determine if this variation in environmental heat is due to a change in the wall temperature. During the third set of calibration tests, a faulty reference junction was found. Based on this anomaly with the reference junction, the heat flux calculations from the first two calibration sets are now considered questionable.

LIQUID OXYGEN (LO2) PROPELLANT CONDITIONING CONCEPT TESTING **c28**

Gretchen L. E. Perry, Michael S. Orth (General Dynamics Corp., Huntsville, AL.), and Gopal K. Mehta (General Dynamics Corp., Huntsville, AL.) *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)

(TABES Paper 93-621) Avail: CASI HC A02/MF A03

Marshall Space Flight Center (MSFC) and industry contractors have undertaken activities to develop a simplified liquid oxygen (LO2) propellant conditioning concept for future expendable launch vehicles. The objective of these activities is to reduce operations costs and timelines and to improve safety of these vehicles. The approach followed has been to identify novel concepts through system level studies and demonstrate the feasibility of these concepts through small-scale and full-scale testing. Testing will also provide data for design guidelines and validation of analytical models. Four different concepts are being investigated: no-bleed, low-bleed, use of a recirculation line, and helium (He) bubbling. This investigation is being done under a Joint Institutional Research and Development (JIRAD) program currently in effect between MSFC and General Dynamics Space Systems (GDSS). A full-scale test article, which is a facsimile of a propellant feed duct with an attached section to simulate heat input from a LO2 turbopump, will be tested at the Cold Flow Facility at MSFC's West Test Area. Liquid nitrogen (LN2), which has similar properties to LO2, will be used in place of LO2 for safety and budget reasons. Work to date includes design and fabrication of the test article, design of the test facility and initial fabrication, development of a test matrix and test procedures, initial predictions of test output, and heat leak calibration and heat exchanger tests on the test article. The tests for all propellant conditioning concepts will be conducted in the summer of 1993, with the final report completed by October, 1993. Author (revised)

APPLYING PAPERLESS TECHNOLOGY TO ACHIEVE EXCELLENCE IN MANUFACTURING OPERATIONS **c81**

Michael Denson and Craig Lykins *In* Huntsville Association of Technical

Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)
(TABES Paper 93-630) Avail: CASI HC A02/MF A03

For manufacturing operations to be competitive in a global market they must integrate new technologies carefully. In the 1980's leading manufacturers spent millions of dollars implementing Paperless Manufacturing Systems. Today, low cost/high performance personal computers, very user friendly software applications, and reliable local area networks make Paperless Manufacturing Systems affordable for the smallest of operations. Widespread use of paperless manufacturing technology will be a driving force in helping U.S. manufacturers compete in the 1990's. Author

THE CLOSING WINDOW OF OPPORTUNITY: ADDRESSING THE US SPACE LAUNCH VEHICLE CRISIS **c15**
Todd Mosher *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 9 p (For primary document see N94-16129 03-38)
(TABES Paper 93-640) Avail: CASI HC A02/MF A03

The United States must decide if it wishes to continue as a leader or assume a lesser role in yet another high technology market. This market is for commercial space launch services and the window of opportunity to remain competitive is quickly eroding. It is clear that the current US space fleet can not meet the schedule demands, operability characteristics or reduced cost requirements to compete with the foreign competition and to meet future launch needs. Almost every recent blue ribbon panel or study has recommended a new launch vehicle development. Yet the US government has failed to embark on a new launch system program. This lack of action is already threatening to put the United States even further behind unless a new program is initiated immediately. The latest incarnation of this idea, the 'Spaceliftер', is a concept that must be embraced and accelerated if the United States is to meet the market challenge. Waiting for 'leap frog' solutions will not allow the commercial industry to survive until its arrival. To ensure that this new space launch system meets its goals and requirements new approaches must be used. These include rapid prototyping of hardware, operational demonstrations to prove the hardware's characteristics and a new industry/government relationship that ensures the maximum efficiency in this austere environment. The United States must take action to remain competitive in the space launch system business or accept a relegated market position. Author

SPACE PROPULSION SYNERGY GROUP ETO TECHNOLOGY ASSESSMENTS **c20**
James Bray *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 9 p (For primary document see N94-16129 03-38)
(TABES Paper 93-641) Avail: CASI HC A02/MF A03

There exists within the aerospace community a widely recognized need to improve future space launch systems. While these needs have been expressed by many national committees, potential solutions have not achieved consensus nor have they endured. Facing the challenge to remain competitive with limited national resources, the U.S. must improve its strategic planning efforts. A nationally accepted strategic plan for space would enable a focused research & development program. The Space Propulsion Synergy Group (SPSG), chartered to support long range strategic planning, has achieved several breakthroughs. First, using a broad industry/government team, the SPSG evaluated and achieved consensus on the vehicles, propulsion systems, and propulsion technologies that have the best long term potential for achieving desired system attributes. The breakthrough that enabled broad consensus was developing criteria that are measurable a-priori. Second, realizing that systems having the best long term payoffs can loose support when constraints are tight, the SPSG invented a dual prioritization approach that balances long term strategic thrusts with current programmatic constraints. This breakthrough enables individual program managers to make decisions based on both individual project needs and long term strategic needs. Results indicate that a SSTO using an integrated modular engine has the best long term potential for a 20 Klb class vehicle and that health monitoring and control technologies rank among the highest dual priority liquid rocket technologies. THE SPACELAB IPS STAR SIMULATOR **c14**
Francis C. Wessling, III *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 4 p (For primary document see N94-16129 03-38)
(Contract NAS8-39400)
(TABES Paper 93-650) Avail: CASI HC A01/MF A03

The cost of doing business in space is very high. If errors occur while in orbit the costs grow and desired scientific data may be corrupted or even lost. The Spacelab Instrument Pointing System (IPS) Star Simulator is a unique test bed that allows star trackers to interface with simulated stars in a laboratory before going into orbit. This hardware-in-the loop testing of equipment on earth increases the probability of success while in space. The IPS Star Simulator provides three fields of view 2.55 x 2.55 degrees each for input into star trackers. The fields of view are produced on three separate monitors. Each monitor has 4096 x 4096 addressable points and can display 50 stars (pixels) maximum at a given time. The pixel refresh rate is 1000 Hz. The spectral output is approximately 550 nm. The available relative visual magnitude range is 2 to 8 visual magnitudes. The star size is less than 100 arc seconds. The minimum star movement is less than 5 arc seconds and the relative position accuracy is approximately 40 arc seconds. The purpose of this paper is to describe the LPS Star Simulator design and to provide an operational scenario so others may gain from the approach and possible use of the system. Author

COST-EFFECTIVE TEST METHODS FOR SHUTTLE PAYLOADS **c16**
Michael L. Tinker *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)
(TABES Paper 93-651) Avail: CASI HC A02/MF A03

Techniques are discussed for deriving constrained vibration mode shapes for space shuttle payloads using unconstrained or free-boundary dynamic properties. Application of the residual flexibility method requires measurement of a set of free boundary modes plus the residual flexibility of the payload-to-orbiter interfaces. The mass-additive approach involves the measurement of unconstrained modes and frequencies of a payload with large masses attached to the interfaces. In either case, the orbiter interfaces of the test-verified payload model are analytically constrained to provide the mode shapes for the shuttle-constrained configuration. Use of these methods or a hybrid combination of them for structures to which they are applicable allows the difficulty and expense associated with development and verification of fixed-base test fixtures to be avoided. GROUND INTEGRATED ET-DERIVED SPACE PLATFORMS FOR ONORBIT APPLICATIONS **c18**
A. R. Pagano, Jr. and E. M. Enright *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 11 p (For primary document see N94-16129 03-38)
(TABES Paper 93-652) Avail: CASI HC A03/MF A03

This paper discusses a departure from the standard approach for deployment and outfitting of a Space Shuttle External Tank (ET) for on-orbit applications. Since the beginning of the development of the ET for the Space Transportation System (STS) project, a multitude of concepts have been proposed for using the ET as a space platform. The design studies are based on three major assumptions: free delivery of the ET to Low Earth Orbit (LEO), availability of the shuttle for outfitting, and extensive use of Extravehicular Activity (EVA) and telerobotics to accomplish the outfitting. However, the design studies have all encountered the following three obstacles: limited availability and timeliness of STS flights, the high cost of EVA, and reduced funding in telerobotic development. The development and use of the ETs for complex space platforms becomes even more imperative with today's space programs facing funding reduction

and/or implementation delays, cancellation, and the possible elimination or reduction in the number of STS flights in favor of various cargo vehicles and the Personnel Launch System (PLS). With these considerations and the assembly problems that influenced all the design studies, a different approach must be found to enable a more near-term realization of using the ET for on-orbit applications. That approach is not to be found in any innovative deployment and outfitting scenarios but in a return to the lessons learned from the Skylab project. An orbiting space lab/platform would be constructed from various modified ET components. The lab could vary in size depending upon how many LH2 tank barrel sections are used. The basic ET structure and tooling would be utilized to assemble a platform based on the customer's requirements. In addition, the equipment and systems for a space lab would be outfitted and tested on the ground before the platform is launched. This method follows the installation and testing procedures currently being used in the commercial satellite industry. The completed space lab/platform would be mated to a launch vehicle and delivered to orbit. Upon insertion into orbit, the lab's solar arrays, radiators, and antennas would be deployed and become fully operational. Without specifying any one particular mission, this paper examines how the modular ET-derived space platforms can offer a number of different configurations for individual users such as commercial enterprises, Government sponsored scientific research, and DoD. MODELING AND SIMULATION: A KEY TO FUTURE DEFENSE TECHNOLOGY **c61**

Anthony B. Muccio *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 5 p (For primary document see N94-16129 03-38)

(TABES Paper 93-654) Avail: CASI HC A01/MF A03

The purpose of this paper is to express the rationale for continued technological and scientific development of the modeling and simulation process for the defense industry. The defense industry, along with a variety of other industries, is currently being forced into making sacrifices in response to the current economic hardships. These sacrifices, which may not compromise the safety of our nation, nor jeopardize our current standing as the world peace officer, must be concentrated in areas which will withstand the needs of the changing world. Therefore, the need for cost effective alternatives of defense issues must be examined. This paper provides support that the modeling and simulation process is an economically feasible process which will ensure our nation's safety as well as provide and keep up with the future technological developments and demands required by the defense industry. The outline of this paper is as follows: introduction, which defines and describes the modeling and simulation process; discussion, which details the purpose and benefits of modeling and simulation and provides specific examples of how the process has been successful; and conclusion, which summarizes the specifics of modeling and simulation of defense issues and lends the support for its continued use in the defense arena. AN ANALYSIS OF THE DYNAMIC RESPONSE OF THE SPACE STATION FREEDOM DUE TO A MODULE PERFORATION BY AN ORBITAL DEBRIS PARTICLE IMPACT **c18**

William P. Schonberg and John P. Celestian *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)

(TABES Paper 93-653) Avail: CASI HC A02/MF A03

The perforation of a habitable module that is part of an extended lifetime space structure in earth orbit by a orbital debris particle will result in a thrust normal to the module surface. The thrust is due to the air exhausting through the hole in the module wall created by the hypervelocity debris particle impact. This paper addresses the global dynamic response of the Space Station Freedom following such a module perforation. By varying the size of the hole through which the module air is allowed to escape, an in-depth study of the dynamic response of the Space Station Freedom to a perforating orbital debris particle impact is performed. An acousto-optic (AO) correlator is being constructed that offers a small, lightweight solution to detecting and analyzing wide-bandwidth, spread-spectrum signals. The processor is being inserted into an existing electronic support measure (ESM) test-bed under the Defense Advanced Research Projects Agency (DARPA) Transition of Optical Processors into Systems (TOPS) program. The correlator has a processing bandwidth of 500 MHz and will be used to detect direct-sequence, phase-modulated signals, frequency-hopped signals, chirps, and impulses. A description of the processor is provided along with experimental results obtained from an interim developmental breadboard. Subsequent digital processing, which includes nonlinear detection and Fourier transformation, is used to determine center frequencies, bandwidths, and band shape. Theoretical descriptions of the post-processing are provided. Author (revised)

WIND TUNNEL INVESTIGATION WITH AN OPERATIONAL TURBOJET ENGINE **c07**

Lamar M. Auman *In* Huntsville Association of Technical Societies, TABES 1993: 9th Annual Technical and Business Exhibition and Symposium 1993 6 p (For primary document see N94-16129 03-38)

(TABES Paper 93-662) Avail: CASI HC A02/MF A03

A wind tunnel test of a turbojet powered missile with the engine installed and operating was conducted in Calspan's Transonic Wind Tunnel in Buffalo, New York from 20 May to 3 June 1991. The primary model configuration consisted of a bifurcated inlet and exhaust which was sting mounted. Instrumentation consisted of a six-component main balance, four fin balances, 39 thermocouples, 10 heat flow gages and several base pressure ports. The purpose of this test was to investigate stability and control, installed engine performance at flight conditions, and plume interactions or aft heating problems. The investigation obtained data at Mach numbers from 0.05 to 0.80, with the majority of the data collected at Mach 0.33, 0.50 and 0.60. Angle of attack was swept from -16 deg to +16 deg, with engine throttle setting, fin deflection angle and Mach number held constant. Missile stability data indicates that the operational mid-body turbojet engine has no adverse effect on missile stability or control authority. Aftbody thermal data indicates that the worst case occurs during a low Mach number (static) high engine throttle setting condition.

THERMAL STRESS EFFECTS IN INTERMETALLIC MATRIX COMPOSITES Final Report

P. K. Wright, M. D. Sensmeier, D. S. Kupperman (Argonne National Lab., IL.), and H. N. G. Wadley (Virginia Univ., Charlottesville.) Sep. 1993 166 p

(Contract NAS3-25790; RTOP 510-01-50)
(NASA-CR-191191; E-8127; NAS 1.26:191191) Avail: CASI HC A08/MF A02

Intermetallic matrix composites develop residual stresses from the large thermal expansion mismatch (delta-alpha) between the fibers and matrix. This work was undertaken to: establish improved techniques to measure these thermal stresses in IMC's; determine residual stresses in a variety of IMC systems by experiments and modeling; and, determine the effect of residual stresses on selected mechanical properties of an IMC. X ray diffraction (XRD), neutron diffraction (ND), synchrotron XRD (SXRD), and ultrasonics (US) techniques for measuring thermal stresses in IMC were examined and ND was selected as the most promising technique. ND was demonstrated on a variety of IMC systems encompassing Ti- and Ni-base matrices, SiC, W, and Al2O3 fibers, and different fiber fractions (Vf). Experimental results on these systems agreed with predictions of a concentric cylinder model. In SiC/Ti-base systems, little yielding was found and stresses were controlled primarily by delta-alpha and Vf. In Ni-base matrix systems, yield strength of the matrix and Vf controlled stress levels. The longitudinal residual stresses in SCS-6/Ti-24Al-llNb composite were modified by thermomechanical processing. Increasing residual stress decreased ultimate tensile strength in agreement with model predictions. Fiber pushout strength showed an unexpected inverse correlation with residual stress. In-plane shear yield strength showed no dependence on residual stress. Higher levels of residual tension led to higher fatigue crack growth rates, as suggested by matrix mean stress effects.

A FUZZY METHOD FOR PRELIMINARY DESIGN RANDOM ACCESS MEMORY FAILURE RATE PREDICTION M.S. Thesis
Keith R. Weyenberg 1992 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267948; AFIT/CI/CIA-93-014) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Preliminary design failure rate predictions tend to be rough approximations due to a lack of sufficient information about components, materials, requirements, etc. Often, experienced engineers can give a qualitative assessment of the possible failure rate of a given design, but have a difficult time quantifying that assessment without the aid of historical data, mathematical equations, or computers. It would be much easier if the experienced engineers judgement or verbal, qualitative evaluations could be converted to quantitative estimates? Fuzzy-set theory provides a method to convert qualitative or subjective evaluations into quantitative ones. This work looks at how fuzzy-set theory can be used to convert qualitative evaluations of factors affecting failure rates into quantitative estimates of failure rates. By using fuzzy estimates of the environment and design effects on failure rate, data is generated by the fuzzy failure rate prediction method.

(NASA-CR-4542; S-734; NAS 1.26:4542) Avail: CASI HC A08/MF A02

A large amount of engineering effort is consumed in conducting experiments to obtain information needed for making design decisions. Efficiency in generating such information is the key to meeting market windows, keeping development and manufacturing costs low, and having high-quality products. The principal focus of this project is to develop and implement applications of Taguchi's quality engineering techniques. In particular, we show how these techniques are applied to reduce the number of experiments for trajectory simulation of the LifeSat space vehicle. Orthogonal arrays are used to study many parameters simultaneously with a minimum of time and resources. Taguchi's signal to noise ratio is being employed to measure quality. A compromise Decision Support Problem and Robust Design are applied to demonstrate how quality is designed into a product in the early stages of designing.

RELIABILITY ANALYSIS OF SURFACE MOUNT TECHNOLOGY (SMT) Final Report, Feb. 1989 - Apr. 1991
Chris A. Myers, Kalyan K. Chakrabarti, Donald H. Merlino, Edward G. Palmer, and Edward F. Pello Mar. 1993 292 p
(Contract F30602-89-C-0057)
(AD-A267598; RL-TR-93-6) Avail: CASI HC A13/MF A03

This report indoctrinates the reader with the understanding of what is involved and necessary in designing and assessing the reliability of surface mount products. Deterministic methods were used to identify the primary design and environmental drivers and statistical methods were used to generate a SMT reliability assessment model. Due to the unavailability of field failure data, finite element analyses (FEA) and environmental test data were used to quantify the model parameters. Information obtained during the model development, internal Harris documents, and military and commercial standards were used to generate design, manufacturing, and quality guidelines. Finally, reliability testing and its correlation to actual life expectancy is addressed to decide the appropriateness of the existing MIL-STD testing requirements and whether these documents need to be modified to correlate to actual life conditions more accurately.

ON PREDICTING THE PERSON-IN-WATER DRIFT FOR SEARCH AND RESCUE Final Report, 15 Nov. 1990 - 31 Mar. 1993
Tsung-Chow Su 1993 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1420)
(AD-A268083) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Search and rescue of people in distress on the high seas requires the capability to accurately predict the position of the survivors. The current approaches on drift prediction are based on an empirical correlation between wind speed and person motion from limited field data. Currently, there is no drift data available for a person wearing a survival suit. Consequently, there is not sufficient data for accurate prediction and this complicates the search and rescue operation. A study is being undertaken at Florida Atlantic University in which the essential effects of environmental forces and person-in-water characteristics will be calculated. The study is intended to provide a theoretical framework for a better understanding of the dynamics of drift and will thus lead to a reliable model of drift prediction and improved efficiency in search and rescue mission. The study consists of the following components: the development of a mathematical model for the drift prediction problem, laboratory studies of drift forces, and field experiments to calibrate the mathematical models and to verify the model prediction.

X RAY COMPUTED TOMOGRAPHY FOR FAILURE ANALYSIS INVESTIGATIONS Interim Report, Sep. 1991 - Apr. 1993
Richard H. Bossi and William Shepherd May 1993 40 p Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(Contract F33615-88-C-5404)
(AD-A268086; WL-TR-93-4047) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Failure analysis is an important engineering evaluation in any product development cycle; it is essential to product reliability and evolution. The volumetric feature detection and three-dimensional positioning capability of X-ray computed tomography are valuable and cost saving assets to a failure analysis laboratory. Savings are realized in reduced risk, determination of proper direction for irreversible failure analysis activities, and schedule improvement. Failure analysis laboratories of sufficient size can justify the cost saving benefits of using CT for equipment procurement. Case studies of failure analyses have been demonstrated to the Air Force and industry showing the ability of CT to significantly benefit such studies. In some cases, CT can directly resolve the problem, and in other cases, CT provides key supplemental information for guiding further investigations and reducing the risk of incorrect or incomplete analysis. Examples have included mechanical and electrical system assembly, system internal measurements and fitups, and material damage evaluation. CT also can be applied to

systems to observe the internal positions as a function of test conditions. High resolution (greater than 4 lp/mm) CT with combined radioscopy (real-time radiography) capability is advocated for failure analysis facilities. DTIC

AUTOMATED IMAGE ANALYSIS METHOD FOR THE DETECTION OF CRACKS ON WOOD SURFACE [PINNAN HALKEILUN AUTOMAATTINEN ANALYYSIMENETELMAE]
Timo Lappalainen Jan. 1992 97 p In FINNISH Sponsored by Technology Development Center, Finland, and Technical Research Centre of Finland, Espoo
(VTT-JULK-755; ISBN-9-51-384102-2; ETN-93-94467) Copyright Avail: CASI HC A05/MF A02

An automated image analysis method was developed for the inspection of cracks on wood surfaces and on paint films. The system is capable of both detecting and analyzing the cracks. The automatic method is capable of classifying the average size of the cracks and the quantity of cracking on the scale 0 to 5 (ISO (International Standards Organization) 4628 standard) with an accuracy of +/- 1 compared to visual classification. The inspection algorithms are based on morphological preprocessing and statistical crack recognition. For optimal thresholding, an experimental system was developed. The image acquisition part of the system is based on a monochrome CCD (Charge Coupled Device) matrix camera. The image processing hardware consists of commercial modules. Information about the length, width, area, circumference, and center of mass and moment of each crack is obtained, as well as the sum of the areas of the cracks in proportion to the whole image area and the density number of the cracks based on ISO 4628 standard. The distribution of the widths and lengths of the cracks are also automatically printed on a laser printer. In the first stage, the equipment was used for determinations of the condition of surface treated boards subjected to weather tests. The performance of the system is promising. All cracks on a white paint film are detected reliably. Analysis of dark paint films is difficult because the reflectance properties of small cracks does not differ from the surrounding paint film. The system provides new possibilities to investigate the development of cracks on wood surfaces, for example, during the drying process. It takes about 3 minutes to analyze one image. The approximation of the analysis time is about 15 seconds, when using a special morphological processor and a computer. ESA

X RAY COMPUTED TOMOGRAPHY FOR CASTING DEMONSTRATION
Interim Report, Sep. 1991 - May 1993
Gary E. Georgeson, Richard H. Bossi, and Raymond D. Rempt 1 May 1993 73 p
(Contract F33615-88-C-5404)
(AD-A268084; WL-TR-93-4048) Avail: CASI HC A04/MF A01

Computed tomography (CT) has been applied to cast products demonstrating benefits to product development, dimensional measurements, and critical region evaluation. The CTAD program has produced data in a number of reports demonstrating the quantitative measurement capability of CT and its advantages for castings. CT is a measurement tool which can enable greater use of casting by assuring quality in complex structural applications. CT allows an engineering evaluation of castings for a number of criteria such as internal defects, porosity content, three-dimensional location of features, and internal and external dimensions. As casting complexity and part value increases, the application of CT increases in cost effectiveness relative to other technologies. For critical regions of a casting, CT can be superior to radiography for detail sensitivity and relatively inexpensive. Educational material is needed to aid engineers in understanding the applicability and benefits of CT to their problems. Example stories have been used by the CTAD program to demonstrate the areas of CT application and cost benefits. Readers of the case study stories are able to extrapolate from the examples to their problems and evaluate the benefits that CT may provide them. DTIC

XPS ANALYSIS OF Al/EPDM BONDLINES FROM IUS SRM-1 POLAR BOSSES Final Report
Carol S. Hemminger and Nicholas Marquez 10 Mar. 1993 25 p
(Contract F04701-88-C-0089)
(AD-A266851; TR-93(3464)-1; SMC-TR-93-28) Avail: CASI HC A03/MF A01

A temperature-stress rupture method using partial immersion in liquid nitrogen was developed for the aluminum/EPDM rubber insulation bondline of the IUS SRM-1 polar bosses in order to investigate a corrosion problem. Subsequent XPS analysis of the ruptured bondline followed changes in the locus of failure as corrosion progressed. Samples from the forward polar bosses had a predominantly noncorroded appearance on the ruptured surfaces. The locus of failure was predominantly through the primer layer, which is distinguished by a high concentration of chlorinated hydrocarbon. The aft polar boss segments analyzed were characterized by the presence of corrosion over the entire mid-section of the ruptured aluminum to insulation bondline. The predominant corrosion product detected was aluminum oxide/hydroxide. The corroded bondline sections had significantly higher concentrations of aluminum oxide/hydroxide than the noncorroded areas, and lower concentrations of primer material. The temperature-stress rupture appeared to progress most readily through areas of thickened aluminum oxide/hydroxide infiltrated into the primer layer. In general there was a very good correlation between the calculated Cl:Al atomic % ratio, and the visual characterization of the extent of corrosion. The Cl:Al ratio, which represents the primer to corrosion product ratio at the locus of failure, varied from 0.4 to 47. With only a few exceptions, surfaces with a predominantly noncorroded appearance had Cl:Al ratios greater than 2, and surfaces with a heavily corroded appearance had Cl:Al ratios less than 1. DTIC

SYSTEMATIC STUDY OF EFFECTS OF LOAD MISALIGNMENT IN UNIAXIAL LOW CYCLE FATIGUE TESTING AT HIGH TEMPERATURES
Fathy A. Kandil and Brian F. Dyson Jul. 1991 32 p
(NPL-DMM(A)-27; ETN-93-94548) Copyright Avail: Issuing Activity
(National Physical Lab., Teddington, Middlesex TW11 OLW, England)

The influence of load misalignment in data scatter observed in uniaxial Low Cycle Fatigue (LCF) testing at high temperatures was modeled by considering the mechanisms of bending in rigid grip systems; the types of extensometer used to control the strain amplitude; and the micromechanisms of fatigue crack 'initiation'. By assuming that the scatter in fatigue lifetimes due to material inhomogeneities is negligible, it was possible not only to predict accurately the good repeatability of Nimonic 101 data found within each laboratory taking part in a worldwide LCF round robin exercise, but also to predict the very poor reproducibility between the laboratories. A MODEL FOR NON-LINEAR CREEP AND PHYSICAL AGEING IN PVC
G. D. Dean, P. E. Tomlins, and B. E. Read Mar. 1993 29 p Sponsored by Dept. of Trade and Industry, London, England
(NPL-DMM(A)-91; ETN-93-94549) Copyright Avail: Issuing Activity
(National Physical Lab., Teddington, Middlesex TW11 OLW, England)

An expression for the creep compliance function is derived for an amorphous polymer Polyvinyl Chloride (PVC) in terms of parameters which depend upon the applied stress and the age of the polymer. Relationships for the stress and age dependence of these parameters are investigated with the aim of establishing procedures whereby creep compliances can be derived by calculation over wide ranges of time, stress and age. Expressions for describing the increase of t(sub 0) (the mean retardation time for the creep mechanism) with creep time (apparent reactivation of physical aging) subsequent to the short term response are explored. Calculated creep compliances are compared with experimental data obtained in tension and compression. Differences in creep behavior under tensile and compressive stresses are traced to different magnitudes of two of the parameters in the model. The scope for using the model to calculate creep compliances from an analysis of a limited quantity of experimental creep data is discussed. ESA

FORCED HARMONIC VIBRATION OF THE GENERALLY ORTHOTROPIC CYLINDRICAL SHELL WITH INNER AND OUTER FLUID LOADING
Mark S. Peloquin 25 Nov. 1992 142 p
(AD-A266985; NUWC-NPT-TR-10199) Avail: CASI HC A07/MF A02

This report describes a modeled system comprised of an infinite shell with both inner and outer fluids subject to forced harmonic vibration in the longitudinal (x) and circumferential (0) directions. Two excitations are applied to the outer shell surface: normal pressure, Po, and longitudinal shear stress, Px. The equations of motion are derived, from first principles, for an elastic shell, including a full treatment of bending and rotatory inertia. The fluids are treated as linearly elastic, inviscid media and are subject to the wave equation in three dimensions. The stress-strain relationship for the shell is formulated to enable the treatment of isotropic, specially orthotropic, and generally orthotropic composite materials undergoing plane stress. DTIC

COMPARISON OF LEVEL-1 AND LEVEL-2 BUCKLING AND POSTBUCKLING SOLUTIONS
J. Arbocz Nov. 1992 226 p
(Grant NAGW-2736)
(NASA-CR-194611; NAS 1.26:194611; LR-700; ISBN-90-6275-839-8; ETN-93-94418) Copyright Avail: CASI HC A11/MF A03

The accuracy of the solutions obtained with the Level-1 computational modules of DISDECO (Delft Interactive Shell Design Code) are investigated by comparing them with solutions obtained with ANILISA, a Level-2 computational module. Whereas the Level-1 solutions are based on the use of trigonometric functions to represent the out-of-plane displacement W and involve Galerkin type approximations to reduce the governing partial differential equations to simple algebraic expressions, the Level-2 solutions employ a truncated Fourier expansion in the circumferential direction and solve the resulting ordinary differential equations forming a nonlinear eigenvalue problem by a Stodola like technique. This involves the numerical integration of the set of ordinary differential equations, which in turn makes it possible to satisfy the specified boundary conditions exactly. It is shown that in many applications the Level-1 predictions concerning the critical buckling load of the perfect structure and its imperfection sensitivity are quite accurate and reliable. For those cases where this is not true, it is shown how the pre and postprocessing facilities of DISDECO can be used efficiently to arrive at a reliable prediction. This involves always the use of the Level-2 computational module ANILISA with its rigorous prebuckling solution and its feature which makes it possible to satisfy the specified boundary conditions exactly. ESA

PROGRESS IN THE MODELING OF THE SHOCK RESPONSE AND MITIGATION OF THICK COMPOSITE SHELLS Memorandum Report
C. T. Dyka and P. W. Randles 22 Jul. 1993 58 p
(AD-A267009; NRL/MR/6386-93-7369) Avail: CASI HC A04/MF A01

This report is a continuation of our efforts to develop a methodology for predicting the response of thick composite materials subjected to multi-dimensional shock loadings. A focus of this work was the initiation and evolution of damage in 1D, 2D, and 3D composite structures. In addition, dispersion/viscoelastic models were investigated for 1D structures and implemented. One dimensional damage predictions are made for composite plates subjected to underwater shock. The 1D and 2D continuum damage models are both applied to the impact of a plexiglass flyer and graphite/peek plate, and the results compare very well to experimental data. A new 3D continuum damage theory is developed for thick laminated composite plates. The 3D theory is in part an extension of the 2D transversely isotropic damage theory. However, three dimensional considerations as well as the inefficiencies of modeling individual plies in a thick composite require a slightly different approach. A 3D formulation is developed which applies the damage directly to the stresses, rather than the compliances as in the 2D and 1D theories. DTIC

AN ASSESSMENT OF FINITE-ELEMENT MODELING TECHNIQUES FOR THICK-SOLID/THIN-SHELL JOINTS ANALYSIS

J. B. Min and S. G. Androlake Oct. 1993 30 p Sponsored by NASA, Washington

(NASA-TM-108426; NAS 1.15:108426) Avail: CASI HC A03/MF A01

The subject of finite-element modeling has long been of critical importance to the practicing designer/analyst who is often faced with obtaining an accurate and cost-effective structural analysis of a particular design. Typically, these two goals are in conflict. The purpose is to discuss the topic of finite-element modeling for solid/shell connections (joints) which are significant for the practicing modeler. Several approaches are currently in use, but frequently various assumptions restrict their use. Such techniques currently used in practical applications were tested, especially to see which technique is the most ideally suited for the computer aided design (CAD) environment. Some basic thoughts regarding each technique are also discussed. As a consequence, some suggestions based on the results are given to lead reliable results in geometrically complex joints where the deformation and stress behavior are complicated. Author (revised)

SYSTEMATOLOGY FOR ELASTIC-PLASTIC MATERIAL EQUATIONS BY LARGE DEFORMATIONS ON THE BASIS OF THE COSSERAT-CONTINUUM MODEL Ph.D. Thesis [EINE SYSTEMATIK FUER ELASTISCHE-PLASTISCHE STOFFGLEICHUNGEN BEI GROSSEN VERFORMUNGEN AUF DER BASIS DES COSSERAT-KONTINUUMSMODELLS]

Rainer Sievert 1992 300 p In GERMAN

(Schriftenr-Physikal-Ing-Bd-23; ISBN-3-79-831517-5; ETN-93-94400) Avail: CASI HC A13/MF A03

The classical continuum model is enlarged by the introduction of a rotation as an additional continuum degree of freedom (Cosserat model). The balances of momentum and internal spin were axiomatically derived from the energy conservation law by the principle of equipresence which was applied to the powerfree part of the stress. A theory for the development of elastic/plastic constitutive equations on the basis of the dissipation/inequality with a couple stress tensor as additional strength is presented. A general decomposition of deformation in an elastic and plastic part was used. The strain tensors obey a certain decomposition, if and only if the elastic constitutive laws for the stress tensors possess the same form as in the pure hyperelastic case. Also objective incremental stress strain relations were calculated by differentiating the finite elastic constitutive laws for the stress. Materials with plastic spin, like single crystals, were treated in the framework of Cosserat's continuum theory; the Eulerian plastic spin tensor turns out to be dissipative. Classical elastic-plastic materials with a multiplicative decomposition of strain were considered. A Eulerian (true) relative stress tensor was used for the description. The technical important cases of isochoric yielding and of small elastic strains at large plastic deformations were investigated. ESA

PRELIMINARY ANALYSIS AND DESIGN OPTIMIZATION OF THE SHORT SPACER TRUSS OF SPACE STATION FREEDOM

A. S. Gendy (Akron Univ., OH.), S. N. Patnaik (Ohio Aerospace Inst., Brook Park.), D. A. Hopkins, and L. Berke Aug. 1993 20 p Sponsored by NASA, Washington Original contains color illustrations

(RTOP 474-46-10)

(NASA-TM-4470; E-7653; NAS 1.15:4470) Avail: CASI HC A03/MF A01; 7 functional color pages

The analysis, dynamic simulation, and design optimization of the short spacer truss of the Space Station Freedom are presented in this report. The short spacer truss will be positioned between the integrated equipment assembly (IEA) and another truss, called the long spacer truss, in the Space Station Freedom. During its launch in the Space Shuttle, the truss will be subjected to considerable in-span distributed inertia loads due to shuttle accelerations. The short spacer truss, therefore, has been modeled as a space frame to account for flexural response. Several parameters have been assumed, since the design specifications are in the process of development; hence the results presented should be considered preliminary. However, the automated analysis and design capabilities that have been developed can readily be used to generate an optimum design of the short spacer truss once the actual specifications have been determined. This report includes static and dynamic analyses of the short spacer truss, which have been obtained with the linear elastic code LE-HOST (in these analyses, LE-HOST data files have been automated to facilitate their future use for different design specifications of the short spacer truss); the dynamic animation of the short spacer truss, which has been carried out by using the results of the dynamic analysis and a post-processing feature of the modeling code PATRAN; and the optimum-weight design of the spacer truss, which was obtained under prescribed stress, displacement, and frequency constraints by using the design code COMETBOARDS. Examination of the analysis and design results revealed that the design could be improved if the configuration of the short spacer truss were modified to a certain extent. A modified configuration, which may simplify fabrication, has been suggested. The performance of this configuration has been evaluated and was found to be satisfactory under both static and dynamic conditions. Author (revised)

N94-15710*# National Aeronautics and Space Administration. Marshall Space Flight Center, Huntsville, AL.

A SIMPLISTIC LOOK AT LIMIT STRESSES FROM RANDOM LOADING

H. M. Lee Oct. 1993 22 p

(NASA-TM-108427; NAS 1.15:108427) Avail: CASI HC A03/MF A01

Utilizing a continuous beam model, this report compares the potential stresses imposed on the beam from a random environment with those resulting from a typical static load analysis or test simulation. The Miles' equation used to develop peak response accelerations is shown to become a force equation in the hands of strength assessment personnel. This may prove to be unrealistic since hardware dynamic stresses are related to deflection rather than load. Correlation of the stress state for any static analysis or test with the actual dynamic response stress is strictly dependent upon how well the static deflections simulate the predominant dynamic mode shape. The report proposes that the general shape of this predominant mode, along with the peak response accelerations of major masses be used in strength assessments. From these data, a tailored enforced displacement loading may prove to be more effective in reproducing random induced stresses on flight hardware. Author

USE OF PHOTOSTRESS AND STRAIN GAGES TO ANALYZE BEHAVIOR OF WELDMENTS AND USE OF PHOTOSTRESS AND STRAIN GAGES TO ANALYZE BEHAVIOR OF AN AFT SKIRT TEST SPECIMEN Semiannual Report, 26 Dec. 1992 - 26 Jul. 1993

S. C. Gambrell (Alabama Univ., Tuscaloosa.) and Gerald R. Karr 27 Oct. 1993 15 p Original contains color illustrations

(Grant NAG8-293)

(NASA-CR-194575; NAS 1.26:194575) Avail: CASI HC A03/MF A01; 4 functional color pages

Previous work using Photostress on TIG welded, heat treated specimens of 2219-T87 parent material and 2319 weld material indicated that behavior of the joint can be highly irregular and non-uniform. Welded joints 1.40 inches thick exhibited a totally non-uniform behavior through the weld thickness with the 'wide' side of the weld being much more ductile than the 'narrow' side. It is believed that this difference in behavior through the weld is, in part, caused by procedures used when laying the weld bead. Joints similar to weldments in references 1 and 2 are an integral part of the aft skirt of the SRB of the shuttle. Since the ultimate safety factor for the lower portion of the weld is below the minimum required safety factor, a photostress analysis of this lower portion will be conducted in the vicinity of the weld. A test program using photostress will be conducted in accordance with the project planning document entitled 'Photostress Evaluation Requirements for AFT Skirt Test Article No. 4'.

THE INFLUENCE OF SECONDARY BENDING ON FATIGUE LIFE IMPROVEMENT IN BOLTED JOINTS

R. L. Evans Aug. 1993 38 p

(ARL-RR-14; AR-008-384) Avail: CASI HC A03/MF A01

Secondary bending often occurs in structural joints, and to assess its influence on the fatigue life enhancement technique of hole cold-expansion, an experimental program has been undertaken. The results indicate that

the effect of cold working is substantially reduced in specimens with secondary bending. For any marked extension in fatigue life, additional treatments, for example, the combination of cold expansion and interference fit, are required. Author (revised)

SLIDESURFACES WITH ADAPTIVE NEW DEFINITIONS (SAND) FOR TRANSIENT ANALYSIS
R. G. Whirley and B. E. Engelmann 2 Jun. 1992 19 p Presented at the Winter Annual Meeting of the ASME, Anaheim, CA, 8-13 Nov. 1992
(Contract W-7405-eng-48)
(DE93-014909; UCRL-JC-108924; CONF-921110-50) Avail: CASI HC A03/MF A01

This paper describes some recent developments in adaptive contact algorithms for the transient analysis of penetration and material failure. A failure criterion is defined for volumes of potentially failing material on each side of a contact surface. As material within an element fails, the element is removed from the calculation, and the contact surface is adaptively redefined to include the newly exposed outer material boundary. This contact algorithm admits arbitrary combinations of shell and solid elements to facilitate the representation of composite or honeycomb structures. The algorithms and their application are illustrated with several large-scale simulations using the explicit transient analysis code DYNA3D. DOE

WEIBULL ANALYSIS APPLIED TO THE PULL ADHESION TEST AND FRACTURE OF A METAL-CERAMIC INTERFACE
R. A. Erck, F. A. Nichols, and D. L. Schult (Illinois Univ., Urbana.) Nov. 1992 21 p Presented at the Annual Conference and Exhibition of the Society of Tribologists and Lubrication Engineers, Calgary, Canada, 17-20 Apr. 1993
(Contract W-31-109-eng-38)
(DE93-012913; ANL/MCT/CP-77789; CONF-9304133-1) Avail: CASI HC A03/MF A01

Various adhesion tests have been developed to measure the mechanical bonding of thin coatings deposited on substrates. In the pull test, pins that have been bonded to the coating under test are pulled with increasing force normal to the coating until the coating is pulled from the substrate. For many systems, large scatter in the data is often observed due to uncontrolled defects in the interface and the brittle nature of the pull test. In this study, the applicability of Weibull statistics to the analysis of adhesion of Ag films to vacuum sputter-cleaned zirconia was examined. Data were obtained for smooth and rough substrates for various levels of adhesion. A good fit of the data to the Weibull distribution was observed. The Weibull modulus was found to depend on the roughness of the substrate, but was insensitive to the adhesion strength. DOE

DESIGN OF A CRUCIFORM BEND SPECIMEN FOR DETERMINATION OF OUT-OF-PLANE BIAXIAL TENSILE STRESS EFFECTS ON FRACTURE TOUGHNESS FOR SHALLOW CRACKS
B. R. Bass, J. W. Bryson, W. J. Mcafee, W. E. Pennell, and T. J. Theiss 1993 12 p Presented at the 12th Biennial Conference for the International Association for Structural Mechanics in Reactor Technology (SMIRT 12), Stuttgart, Germany, 16-26 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015455; CONF-930803-13) Avail: CASI HC A03/MF A01

Pressurized-thermal-shock loading in a reactor pressure vessel produces significant positive out-of-plane stresses along the crack front for both circumferential and axial cracks. Experimental evidence, while very limited, seems to indicate that a reduction in toughness is associated with out-of-plane biaxial loading when compared with toughness values obtained under uniaxial conditions. A testing program is described that seeks to determine the effects of out-of-plane biaxial tensile loading on fracture toughness of RPV steels. A cruciform bend specimen that meets specified criteria for the testing program is analyzed using three-dimensional elastic-plastic finite-element techniques. These analysis results provide the basis for proposed test conditions that are judged likely to produce a biaxial loading effect in the cruciform bend specimen. DOE

A NOVEL APPROACH FOR STRUCTURAL MECHANICS PROBLEMS WITH STOCHASTICITY Final Report, 15 Oct 1990 - 14 Jan. 1993
Pol D. Spanos and L. B. Ryon 18 Apr. 1993 58 p
(Grant AF-AFOSR-0004-91)
(AD-A266189; AFOSR-93-0430TR) Avail: CASI HC A04/MF A01

Considerable advances were made in several structural mechanics problems with stochasticity. First, a new method was developed for the solution of problems involving material variability. The Karhunen-Loeve expansion was used for this purpose. Further, a problem involving a plate with a curved boundary was solved. Also methods unifying the theory of stochastic and deterministic finite elements were developed. In parallel, a method for more efficient Monte-Carlo simulation was developed. Finally, some work in the area-of stochastic finite difference was done. DTIC

ON THE DESIGN OF STRUCTURAL COMPONENTS USING MATERIALS WITH TIME-DEPENDENT PROPERTIES
Pedro I. Rodriguez Oct. 1993 55 p
(NASA-TM-108428; NAS 1.15:108428) Avail: CASI HC A04/MF A01

The application of the elastic-viscoelastic correspondence principle is presented as a design tool for structural design engineers for composite material applications. The classical problem of cantilever beams is used as the illustration problem. Both closed-form and approximate numerical solutions are presented for several different problems. The application of the collocation method is presented as a viable and simple design tool to determine the time-dependent behavior and response of viscoelastic composite beams under load. Author

HIGHLY TRANSIENT ELASTODYNAMIC CRACK GROWTH IN A BIMATERIAL INTERFACE: HIGHER ORDER ASYMPTOTIC ANALYSIS AND OPTICAL EXPERIMENTS
Cheng Liu, John Lambros, and Ares J. Rosakis 20 Dec. 1992 98 p
(AD-A266465; SM-92-37) Avail: CASI HC A05/MF A02

A higher order asymptotic analysis of the transient deformation field surrounding the tip of a crack running dynamically along a bimaterial interface is presented. An asymptotic methodology is used to reduce the problem to one of the Riemann-Hilbert type. Its solution furnishes displacement potentials which are used to explicitly evaluate the near-tip transient stress field. Crack-tip fields corresponding to crack speeds up to the lower of the two shear wave speeds are investigated. An experimental study of dynamic crack growth in PMMA/steel interfaces using the optical method of CGS and high speed photography, is also described. Transonic terminal speeds (up to 1.4c(sub s)(PMMA) and initial accelerations (approximately 10(exp 8) m/sec(exp 2)) are reported and discussed. Transient effects are found to be severe and more important than in homogeneous dynamic fracture. For subsonic crack growth, these experiments are used to demonstrate the necessity of employing a fully transient expression in the analysis of optical data to accurately predict the complex dynamic stress intensity factor history. FINITE ELEMENT ANALYSIS OF STRUCTURAL ENGINEERING PROBLEMS USING A VISCOPLASTIC MODEL INCORPORATING TWO BACK STRESSES

Vinod K. Arya (Toledo Univ., OH.) and Gary R. Halford Oct. 1993 26 p
(RTOP 505-63-5B)
(NASA-TM-106046; E-7922; NAS 1.15:106046) Avail: CASI HC A03/MF A01

The feasibility of a viscoplastic model incorporating two back stresses and a drag strength is investigated for performing nonlinear finite element analyses of structural engineering problems. To demonstrate suitability for nonlinear structural analyses, the model is implemented into a finite element program and analyses for several uniaxial and multiaxial problems are performed. Good agreement is shown between the results obtained using the finite element implementation and those obtained experimentally. The advantages of using advanced viscoplastic models for performing nonlinear finite element analyses of structural components are indicated. Author (revised)

FATIGUE LIFE PROGRAM USING STRAIN-LIFE METHODS M.S. Thesis

Michael V. Skelly 25 Mar. 1993 91 p
(AD-A267310) Avail: CASI HC A05/MF A01

A user friendly program was developed to calculate fatigue life using Strain-Life equations, given either a stress history or a strain history. Additionally, the material parameters and associated stress concentration factors can be varied. Since certain material constants, such as cyclic strength coefficient (K') and cyclic strain hardening exponent (n') vary during a material's fatigue life, the program is capable of either keeping them constant or varying them as a function of elapsed cycles. The program was then utilized to examine the effects of varying K' and n' on the calculated fatigue life of aluminum 7075-T6 under a typical flight load history. DTIC

INTERFACIAL SHEAR BEHAVIOR AND ITS INFLUENCE ON FIBER DAMAGE IN SAPPHIRE-REINFORCED GAMMA TITANIUM ALUMINIDE COMPOSITES Ph.D. Thesis

Jay M. Galbraith May 1993 200 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267943; AFIT/CI/CIA-93-001D) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The interfacial shear behavior and its influence on fiber damage in sapphire-reinforced TiAl composites was investigated using a combination of microscopic characterization, indentation crack growth results, fiber pushout testing, fiber displacement measurements, and computational analyses. Two inter-related phenomena were studied: (1) residual stresses and resulting damage within fibers intersecting a free surface and (2) fiber/matrix interfacial strength behavior. In the first aspect of this study, experimental observations, finite element analysis, as well as analytical computations were all used to analyze the evolution of fiber damage that was observed in fibers intersecting a free surface in sapphire-reinforced Ti-48Al-4 composites. Experimental observations indicate that, under certain conditions, surface cracks introduced during specimen preparation will propagate along the fiber axis due to thermally-induced residual stresses. Finite element computations predict that significant thermally-induced residual tensile stresses exist in sapphire fibers embedded within TiAl-based matrices when they intersect and are oriented normal to a free surface. Indentation crack growth behavior within the sapphire fibers provided experimental validation of the predicted stress state. Finally, the application of an exact elastic analysis indicates that tensile stresses also exist within fibers oriented parallel to and near a free surface. DTIC

INFLUENCE OF THE LOADING RATE ON THE ENDURANCE AND DEFORMABILITY OF CEMENT MATRIX COMPOSITES [WPLYW PREDKOSCI OBCIAZENIA NA WYTRZYMALOSC I ODKSZTALCALNOSC KOMPOZYTOW Z MATRYCA CEMENTOWA]

Michal A. Glinicki 1992 242 p In POLISH
(IFTR-1/1992) Avail: CASI HC A11/MF A03

Results are presented of the author's experiments on the strength and deformation of composites with a cement matrix at various loading rates ranging from 10(exp -3) to 10(exp +3) MPa/s. The studies involved composites with a Portland cement base. The goal was to find the qualitative and quantitative effect of the loading rate sigma on the behavior of composites subjected to axial tension. Specifically, the studies were done to determine the sensitivity differences of composites to loading rate when these materials were used for outside construction. The effect of changes in the deformation parameters and failure with varying sigma was understood to represent sensitivity. Structural attributes of composites with a cement matrix are described in Section 2; Section 1 reviews the current state of knowledge on deformation and cracking of these composites under static and dynamic tensile loads. The experimental method in the study is described in Section 4. The structure of selected model composites revealed in a clinical way analyzed traits such as: porosity, granulation of the aggregate and content and orientation of fiber reinforcement. Apparent density, density, and porosity were identified in each of the five types of composites. Studies of direct tensile loading were carried out at rates of 0.002, 1.0, 50 and 850 MPa/s. A digital image analyzer was used for quantitative analysis of sample sections. Results are presented in Section 5; in Section 6, results are analyzed and compared to results obtained by other investigators. The results justify the theory on the significant effect of structural parameters of composites on changes in strength and resistance to damage due to changes in a under tensile loading. Increase in the rate of loading causes a definite increase in resistance to tensile motion f(sub t) as well as to deformation of the limit epsilon(sub u) of the composites. In composites with fiber reinforcement, an increase in sigma also causes an increase in failure energy. Composite porosity is the most significant structural property of these materials that affects the sensitivity to loading rate with respect to f(sub t). This sensitivity loading rate increases with increasing composite porosity. As a model (Section 7), a proposal is made that the effect of composite porosity on their sensitivity to the loading rate be interpreted with respect to f(sub t). It is demonstrated that a good agreement with experimental results can be obtained by accepting the principle that precritial cracks decrease in size increasing loading rate and that there is an increase

in loccal dispersion of material quality due to porosity. Conclusions and postulates pertaining to the direction of subsequent studies are presented in the conclusion. Transl. by FLS

ELASTIC WAVES IN DISCRETELY CONTINUOUS MECHANICAL SYSTEMS [FALE SPREZYSTE W DYSKRETNO-CIAGLYCH UKLADACH MECHANICZNYCH]

Amalia Pielorz 1992 172 p In POLISH

(IFTR-21/1992) Avail: CASI HC A08/MF A02

Focus is on research on dynamic displacement and deformation of selected linear and non-linear discrete-continuous mechanical systems utilizing linear elasticity waves. The first portion of the study presents results from two and three dimensional wave problems of circular rolls and the possibility for their application to discrete-continuous mechanical systems under both longitudinal and transverse torsional strain. The second section of the study presents a method of finding displacement at deformation in discrete-continuous mechanical systems consisting of rotationally- or longitudinally-strained elastic elements of variable and fixed cross section connected by rigid bodies. This method is based on the use of one-dimensional elasticity waves. The method makes it possible to utilize an integrated calculation apparatus for analyzing temporary motion and steady state motion. This method is illustrated based on a linear drive system containing multiple masses for the case of longitudinally-colliding linear bar subsystems and for the case of a drive system with multiple masses with a local non-linearity. Wave solutions of equations of motion and corresponding numerical methods were used to determine the displacement. Analytic results are also given for particular linear cases of discrete-continuous mechanical systems. The proposed wave method is compared to the rigid finite element method and the separation of variables method. Transl. by FLS

MEASUREMENT AND THEORY OF THE DEPENDENCE OF HARDNESS ON RESIDUAL STRESS Final Report

A. Abbate, J. Frankel, and W. Scholz May 1993 33 p

(AD-A267553; ARCCB-TR-93022) Avail: CASI HC A03/MF A01

The Rockwell C hardness (Rc) was measured as a function of position on the three steel rings cut from tubes with different amounts of autofrettage. These rings had different residual stress profiles through the wall that were measured using an ultrasonic technique. An experimental correlation between residual stress and Rc was obtained. In order to model the effects of residual stress on the measured hardness, the Tresca (linear) and the von Mises-Hencky (power) yield criteria were utilized within a model given by Shaw, Hoshi, and Henry that depicts the stress state within a spherical indenter. The von Mises-Hencky method was more successful in matching the data. DTIC

DEVELOPMENT AND COMPARISON OF ADVANCED REDUCED-BASIS METHODS FOR THE TRANSIENT STRUCTURAL ANALYSIS OF UNCONSTRAINED STRUCTURES

David M. McGowan, Susan W. Bostic, and Charles J. Camarda Nov. 1993 30 p

(RTOP 537-06-21-09)

(NASA-TM-109015; NAS 1.15:109015) Avail: CASI HC A03/MF A01

The development of two advanced reduced-basis methods, the force derivative method and the Lanczos method, and two widely used modal methods, the mode displacement method and the mode acceleration method, for transient structural analysis of unconstrained structures is presented. Two example structural problems are studied: an undamped, unconstrained beam subject to a uniformly distributed load which varies as a sinusoidal function of time and an undamped high-speed civil transport aircraft subject to a normal wing tip load which varies as a sinusoidal function of time. These example problems are used to verify the methods and to compare the relative effectiveness of each of the four reduced-basis methods for performing transient structural analyses on unconstrained structures. The methods are verified with a solution obtained by integrating directly the full system of equations of motion, and they are compared using the number of basis vectors required to obtain a desired level of accuracy and the associated computational times as comparison criteria. ELASTIC-PLASTIC FINITE-DIFFERENCE ANALYSIS OF UNIDIRECTIONAL COMPOSITES SUBJECTED TO THERMOMECHANICAL CYCLIC LOADING Final Report, 1 Jan. - 1 Dec. 1992

Demirkan Coker and Noel E. Ashbaugh Dec. 1992 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F33615-91-C-5606)

(AD-A267666; WL-TR-93-4043) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An analytical tool was developed to model a unidirectional composite subjected to thermomechanical cyclic loading and processing conditions. The finite difference method was incorporated into a PC compatible computer code, FIDEP (Finite-Difference Code for Elastic-Plastic Analysis of Composites). FIDEP provides an efficient numerical procedure for analyzing a variety of problems involving thermal and mechanical cycling. The procedure allows the modeling of the constituent materials as elastic-plastic with temperature dependent properties. The concentric cylinder

approximation allows the computations to capture the three-dimensional aspects of the stress state in a real composite. Results for a thermal cool-down in an SCS-6/Ti-24Al-11Nb unidirectional composite compare well with those obtained using the finite element method. Several problems were solved for thermomechanical loading conditions and demonstrate the three-dimensional nature of the stress fields in the matrix material. DTIC

FLUTTER ANALYSIS USING TRANSVERSALITY THEORY

D. Afolabi Nov. 1993 24 p

(Contract NCC3-233; RTOP 505-90-5K)

(NASA-TM-106382; ICOMP-93-43; E-8200; NAS 1.15:106382) Avail: CASI HC A03/MF A01

A new method of calculating flutter boundaries of undamped aeronautical structures is presented. The method is an application of the weak transversality theorem used in catastrophe theory. In the first instance, the flutter problem is cast in matrix form using a frequency domain method, leading to an eigenvalue matrix. The characteristic polynomial resulting from this matrix usually has a smooth dependence on the system's parameters. As these parameters change with operating conditions, certain critical values are reached at which flutter sets in. Our approach is to use the transversality theorem in locating such flutter boundaries using this criterion: at a flutter boundary, the characteristic polynomial does not intersect the axis of the abscissa transversally. Formulas for computing the flutter boundaries and flutter frequencies of structures with two degrees of freedom are presented, and extension to multi-degree of freedom systems is indicated. The formulas have obvious applications in, for instance, problems of panel flutter at supersonic Mach numbers. Author

THE PHOTONICAL, PURE GRID METHOD

Pieter J. Sevenhuijsen 9 Dec. 1992 29 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(NLR-TP-91478-U; ETN-93-94785) Avail: CASI HC A03

An introduction to the pure grid method for deformation measurements in experimental mechanics is presented. The pure grid method involves that the grid images are processed separately and subsequently the results of these separate processings are substrated from each other in order to obtain a quantified deformation indication. Nowadays, the recording and processing of the grid images can be performed photonically by means of digital image measurement systems. The basic data processing relations and set ups of four different applicabilities are discussed. Strains can be measured with errors smaller than 200 microstrain and displacements with errors smaller than 1/50,000 of the diameter of the object as visible in the grid image. These figures can be improved substantially by future application of high resolving power Charge Coupled Device (CCD) cameras. Two examples are shown. An extensive bibliography for further explorations is also presented. ESA

SHEAR WAVE MEASUREMENTS IN SHOCK-INDUCED, HIGH-PRESSURE PHASES

J. B. Aidun 1993 5 p Presented at the 14th International Conference on High Pressure Science and Technology and 1993 Technical Meeting of the Topical Group on Shock Compression of Condensed Matter, Colorado Springs, CO, 28 Jun. - 3 Jul. 1993

(Contract W-7405-eng-36)

(DE93-016461; LA-UR-93-2319; CONF-9306167-9) Avail: CASI HC A01/MF A01

Structural phase transformations under shock loading are of considerable interest for understanding the response of solids under nonhydrostatic stresses and at high strain-rates. Examining shock-induced transformations from continuum level measurements is fundamentally constrained by the inability to directly identify microscopic processes, and also by the limited number of material properties that can be directly measured. The latter limitation can be reduced by measuring both shear and compression waves using Lagrangian gauges in combined, compression and shear loading. The shear wave serves as an important, real-time probe of the shocked state and unloading response. Using results from a recent study of CaCO3, the unique information obtained from the shear wave speed and the detailed

structure of the shear wave are shown to be useful for distinguishing the effects of phase transformations from yielding, as well as in characterizing the high-pressure phases and the yielding process under shock loading.

This publication contains the preliminary agenda and summaries for the Third Annual JPL Airborne Geoscience Workshop, held at the Jet Propulsion Laboratory, Pasadena, California, on 1-5 June 1992. This main workshop is divided into three smaller workshops as follows: (1) the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) workshop, on June 1 and 2; the summaries for this workshop appear in Volume 1; (2) the Thermal Infrared Multispectral Scanner (TIMS) workshop, on June 3; the summaries for this workshop appear in Volume 2; and (3) the Airborne Synthetic Aperture Radar (AIRSAR) workshop, on June 4 and 5; the summaries for this workshop appear in Volume 3. For individual titles, see N94-16596 through N94-16608.

TIMS PERFORMANCE EVALUATION SUMMARY **c43**
Bruce Spiering, G. Meeks, J. Anderson, S. Jaggi, and S. Kuo *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 1-3 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

The purpose of this effort was to investigate the Thermal Infrared Multispectral Scanner (TIMS) operation under various conditions to determine what effect, if any, there is on the TIMS performance. This effort was undertaken because of reports from investigators that the TIMS is not performing as expected when flown on the ARC C-130. This effort was initiated with a meeting at Stennis Space Center (SSC) with representatives from SSC, Jet Propulsion Laboratory (JPL), and ARC. Author (revised)

A QUANTITATIVE ANALYSIS OF TIMS DATA OBTAINED ON THE LEARJET 23 AT VARIOUS ALTITUDES **c43**
S. Jaggi *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 4-6 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

A series of Thermal Infrared Multispectral Scanner (TIMS) data acquisition flights were conducted on the NASA Learjet 23 at different altitudes over a test site. The objective was to monitor the performance of the TIMS (its estimation of the brightness temperatures of the ground scene) with increasing altitude. The results do not show any significant correlation between the brightness temperatures and the altitude. The analysis indicates that the estimation of the temperatures is a function of the accuracy of the atmospheric correction used for each altitude.

ANALYSIS OF TIMS PERFORMANCE SUBJECTED TO SIMULATED WIND BLAST **c43**
S. Jaggi and S. Kuo *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 7-9 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

The results of the performance of the Thermal Infrared Multispectral Scanner (TIMS) when it is subjected to various wind conditions in the laboratory are described. Various wind conditions were simulated using a 24 inch fan or combinations of air jet streams blowing toward either or both of the blackbody surfaces. The fan was used to simulate a large volume of air flow at moderate speeds (up to 30 mph). The small diameter air jets were used to probe TIMS system response in reaction to localized wind perturbations. The maximum nozzle speed of the air jet was 60 mph. A range of wind directions and speeds were set up in the laboratory during the test. The majority of the wind tests were conducted under ambient conditions with the room temperature fluctuating no more than 2 C. The temperature of the high speed air jet was determined to be within 1 C of the room temperature. TIMS response was recorded on analog tape. Additional thermistor readouts of the blackbody temperatures and thermocouple readout of the ambient temperature were recorded manually to be compared with the housekeeping data recorded on the tape. Additional tests were conducted under conditions of elevated and cooled room temperatures. The room temperature was varied between 19.5 to 25.5 C in these tests. The calibration parameters needed for quantitative analysis of TIMS data were first plotted on a scanline-by-scanline basis. These parameters are the low and high blackbody temperature readings as recorded by the TIMS and their corresponding digitized count values. Using these values, the system transfer equations were calculated. This equation allows us to compute the flux for any video count by computing the slope and intercept of the straight line that relates the flux to the digital count. The actual video of the target (the lab floor in this case) was then compared with a simulated target. This simulated target was assumed to be a blackbody at emissivity of .95 degrees and the temperature was assumed to be at ambient temperature as recorded by the TIMS for each scanline. Using the slope and the intercept the flux corresponding to this target was converted into digital counts. The counts were observed to have a strong correlation with the actual video as recorded by the TIMS. The attached graphs describe the performance of the TIMS when compressed air is blown at each one of the blackbodies at different speeds. The effect of blowing a fan and changing the room temperature is also being analyzed. Results indicate that the TIMS system responds to variation in wind speed in real time and maintains the capability to produce accurate temperatures on a scan line basis.

SENSITIVITY OF BLACKBODY REFERENCE PANELS TO WIND BLAST **c43**
Gordon Hoover *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 10-12 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

As part of the effort at Stennis and JPL to discover the root causes of Thermal Infrared Multispectral Scanner's (TIMS') temperature calibration errors, a series of experiments were performed to measure the sensitivity of a heated plate to cooling by wind blast. A powerful blower which was capable of generating a jet of wind in excess of 200 miles per hour was set up. In the jet, an electrically heated copper plate, one quarter of an inch thick and six inches square, was mounted. The electrical heaters were capable of delivering a total power of 800 watts. The power to the

heaters was feedback controlled with reference to a thermistor mounted on the back of the copper plate. The plate was mounted about 2.5 feet from the blower nozzle, at about 45 deg to the direction of the jet. The jet was wide enough to wash the whole surface and its temperature at the plate was about 28 C. Author (revised)

COMPARISON OF PRELIMINARY RESULTS FROM AIRBORNE ASTER SIMULATOR (AAS) WITH TIMS DATA **c43**
Yoshiaki Kannari, Franklin Mills, Hiroshi Watanabe, Teruya Ezaka, Tatsuhiko Narita, and Sheng-Huei Chang (Geophysical and Environmental Research, Inc., New York, NY.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 13-15 Sponsored in part by Japan Resources Observation System Organization (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

The Japanese Advanced Spaceborne Thermal Emission and Reflection radiometer (ASTER), being developed for a NASA EOS-A satellite, will have 3 VNIR, 6 SWIR, and 5 TIR (8-12 micron) bands. An Airborne ASTER Simulator (AAS) was developed for Japan Resources Observation System Organization (JAROS) by the Geophysical Environmental Research Group (GER) Corp. to research surface temperature and emission features in the MWIR/TIR, to simulate ASTER's TIR bands, and to study further possibility of MWIR/TIR bands. ASTER Simulator has 1 VNIR, 3 MWIR (3-5 microns), and 20 (currently 24) TIR bands. Data was collected over 3 sites - Cuprite, Nevada; Long Valley/Mono Lake, California; and Death Valley, California - with simultaneous ground truth measurements. Preliminary data collected by AAS for Cuprite, Nevada is presented and AAS data is compared with Thermal Infrared Multispectral Scanner (TIMS) data. Author (revised)

APPLICATION OF SPLIT WINDOW TECHNIQUE TO TIMS DATA **c43**
Tsuneo Matsunaga, Shuichi Rokugawa, and Yoshinori Ishii *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 16-18 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

Absorptions by the atmosphere in thermal infrared region are mainly due to water vapor, carbon dioxide, and ozone. As the content of water vapor in the atmosphere greatly changes according to weather conditions, it is important to know its amount between the sensor and the ground for atmospheric corrections of thermal Infrared Multispectral Scanner (TIMS) data (i.e. radiosonde). On the other hand, various atmospheric correction techniques were already developed for sea surface temperature estimations from satellites. Among such techniques, Split Window technique, now widely used for AVHRR (Advanced Very High Resolution Radiometer), uses no radiosonde or any kind of supplementary data but a difference between observed brightness temperatures in two channels for estimating atmospheric effects. Applications of Split Window technique to TIMS data are discussed because availability of atmospheric profile data is not clear when ASTER operates. After these theoretical discussions, the technique is experimentally applied to TIMS data at three ground targets and results are compared with atmospherically corrected data using LOWTRAN 7 with radiosonde data. Avail: CASI HC A01/MF A01

The estimated temperature of the average of 500 lines of Thermal Infrared Multispectral Scanner (TIMS) data of the Pacific Ocean, from flight line 94, collected on 30 Sep. 1988, at 1931 GMT is shown. With no atmospheric corrections, estimated temperature decreases away from nadir (the center of the scan line). A LOWTRAN modeled correction, using local radiosonde data and instrument scan angle information, results in reversed limb darkening effects for most bands, and does not adequately correct all bands to the same temperature. The atmosphere tends to re-radiate energy at the wavelengths at which it most absorbs, and thus the overall difference between corrected and uncorrected temperatures is approximately 40 C, despite the average LOWTRAN calculated transmittance of only 60 percent between 8.1 and 11.6 microns. An alternative approach to atmospheric correction is a black body normalization. This is done by calculating a normalization factor for each pixel position and wavelength, which when applied results in a single calculated temperature, as would be expected for a gray body with near uniform emittance. The black body adjustment is based on the atmospheric conditions over the sea. The ground elevation profile along the remaining 3520 scan lines (approximately 10 km) of flight line 94, up the slopes of Kilauea, determined from aircraft pressure and laser altimeter data is shown. This flight line includes a large amount of vegetation that is clearly discernible on the radiance image, being much cooler than the surrounding rocks. For each of the 3520 scan lines, pixels were classified as vegetation or 'other'. A moving average of 51 lines was applied to the composite vegetation emittance for each scan line, to reduce noise. Assuming vegetation to be like water, and to act as gray body with an emittance of 0.986 across the spectrum, it is shown that that the LOWTRAN induced artifacts are severe, and other than for the 0.9.9 micron channel, not significantly different from applying no corrections at all. As expected, with increasing elevation atmospheric effects are slightly reduced, because moisture tends to be concentrated in the lowermost part of the atmosphere. The black body adjustment is highly robust, and even at elevations nearly 600 meters above the sea, remains an alternative procedure for use in calculating emittance. Author (revised)

AN ALGORITHM FOR THE ESTIMATION OF BOUNDS ON THE EMISSIVITY AND TEMPERATURES FROM THERMAL MULTISPECTRAL AIRBORNE REMOTELY SENSED DATA **c43**
S. Jaggi (Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.), D. Quattrochi, and R. Baskin (Geological Survey, Salt Lake City, UT.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 22-24 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

The effective flux incident upon the detectors of a thermal sensor, after it has been corrected for atmospheric effects, is a function of a non-linear combination of the emissivity of the target for that channel and the temperature of the target. The sensor system cannot separate the contribution from the emissivity and the temperature that constitute the flux value. A method that estimates the bounds on these temperatures and emissivities from thermal data is described. This method is then tested with remotely sensed data obtained from NASA's Thermal Infrared Multispectral Scanner (TIMS) - a 6 channel thermal sensor. Since this is an under-determined set of equations i.e. there are 7 unknowns (6 emissivities and 1 temperature) and 6 equations (corresponding to the 6 channel fluxes), there exist theoretically an infinite combination of values of emissivities and temperature that can satisfy these equations. Using some realistic bounds on the emissivities, bounds on the temperature are calculated. These bounds on the temperature are refined to estimate a tighter bound on the emissivity of the source. An error analysis is also carried out to quantitatively determine the extent of uncertainty introduced in the estimate of these parameters. This method is useful only when a realistic set of bounds can be obtained for the emissivities of the data. In the case of water the lower and upper bounds were set at 0.97 and 1.00 respectively. Five flights were flown in succession at altitudes of 2 km (low), 6 km (mid), 12 km (high), and then back again at 6 km and 2 km. The area selected with the Ross Barnett reservoir near Jackson, Mississippi. The mission was flown during the predawn hours of 1 Feb. 1992. Radiosonde data was collected for that duration to profile the characteristics of the atmosphere. Ground truth temperatures using thermometers and radiometers were also obtained over an area of the reservoir. The results of two independent runs of the radiometer data averaged 7.03 plus or minus .70 for the first run and 7.31 plus or minus .88 for the second run. The results of the algorithm yield a temperature of 7.68 for the low altitude data to 8.73 for the high altitude data. Author (revised)

MULTI-RESOLUTION PROCESSING FOR FRACTAL ANALYSIS OF AIRBORNE REMOTELY SENSED DATA **c43**

S. Jaggi (Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.), D. Quattrochi, and N. Lam (Louisiana State Univ., Baton Rouge.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 25-27 (For primary document see N94-16595 03-42)

Avail: CASI HC A01/MF A01

Fractal geometry is increasingly becoming a useful tool for modeling natural phenomenon. As an alternative to Euclidean concepts, fractals allow for a more accurate representation of the nature of complexity in natural boundaries and surfaces. Since they are characterized by self-similarity, an ideal fractal surface is scale-independent; i.e. at different scales a fractal surface looks the same. This is not exactly true for natural surfaces. When viewed at different spatial resolutions parts of natural surfaces look alike in a statistical manner and only for a limited range of scales. Images acquired by NASA's Thermal Infrared Multispectral Scanner are used to compute the fractal dimension as a function of spatial resolution. Three methods are used to determine the fractal dimension - Schelberg's line-divider method, the variogram method, and the triangular prism method. A description of these methods and the results of applying these methods to a remotely-sensed image is also presented. Five flights were flown in succession at altitudes of 2 km (low), 6 km (mid), 12 km (high), and then back again at 6 km and 2 km. The area selected was the Ross Barnett reservoir near Jackson, Mississippi. The mission was flown during the predawn hours of 1 Feb. 1992. Radiosonde data was collected for that duration to profile the characteristics of the atmosphere. This corresponds to 3 different pixel sizes - 5m, 15m, and 30m. After, simulating different spatial sampling intervals within the same image for each of the 3 image sets, the results are cross-correlated to compare the extent of detail and complexity that is obtained when data is taken at lower spatial intervals.

PRELIMINARY ANALYSIS OF THERMAL-INFRARED MULTISPECTRAL SCANNER DATA OF THE IRON HILL, COLORADO CARBONATITE-ALKALIC ROCK COMPLEX **c43**

Lawrence C. Rowan, Kenneth Watson (Geological Survey, Denver, CO.), and Susanne H. Miller (Geological Survey, Denver, CO.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 28-30 (For primary document see N94-16595 03-42)

Avail: CASI HC A01/MF A01

The Iron Hill carbonatite-alkalic igneous rock complex is in the Powderhorn mining district, approximately 40 km south-southwest of Gunnison, Colorado. The complex, which occupies about 30 sq km, was emplaced in metasedimentay and metavolcanic rocks during the later Precambrian or early Cambrian. The main rock types in the complex, from oldest to youngest, are fenite, pyroxenite, uncompahgrite, ijolite, nepheline syenite, and dolomitic carbonatite. The carbonatite is limonitic and forms an elliptially shaped 4 sq km stock. Calcitic and dolomitic carbonatite dikes are also numerous throughout the complex and in the pre-existing rocks. Pyroxenite is the most widespread rock type within the complex, but pyroxene is extensively altered to biotite, phlogopite, and vermiculite. Fenite, which formed through Na, K-metasomatism of the country rocks, typically contains more feldspar and less quartz than the equivalent unaltered country rocks. The other alkalic rock types are less widespread and less well exposed. Parts of the complex are covered by Oligocene ash-flow tuff and alluvial, colluvial, and glacial deposits. Sagebrush and grass cover is moderately dense to very dense at low to intermediate elevations; coniferous tree cover is dense at high elevations and on some north-facing slopes at lower elevations. A new algorithm was used to compute spectral emissivity ratios, independent of any emissivity assumptions. This algorithm has the advantage that any of the possible emissivity ratios can be computed and, thus, a large variety of composite ratio images can be constructed, which permits examination of various geologic hypotheses based on the spectral properties of the surface materials. THE USE OF TIMS FOR MAPPING DIFFERENT PAHOEHOE SURFACES: MAUNA IKI, KILAUEA **c43**

Scott K. Rowland *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 31-33 (For primary document see N94-16595 03-42)

Avail: CASI HC A01/MF A01

S-type and p-type pahoehoe record different mechanisms and vigors of activity within an active flow field. There is some controversy about what these mechanisms are exactly, and this study was undertaken with the idea that an accurate map of the two surfaces within a pahoehoe flow field could be helpful in solving the problem. Thermal Infrared Multispectral Scanner (TIMS) allows discrimination between s-type and p-type pahoehoe, and this ability was used to map the two surface types on the Mauna Iki satellite shield (southwest rift zone, Kilauea Volcano). TIMS was previously used to discriminate a'a from pahoehoe as well as to determine relative age relationships of different flows. Although inter-flow variation was minor in the data published by these authors, a second goal presented is to understand such variations to better constrain intra-flow differences used for age dating. EJECTA PATTERNS OF METEOR CRATER, ARIZONA DERIVED FROM THE LINEAR UN-MIXING OF TIMS DATA AND LABORATORY THERMAL EMISSION SPECTRA **c43**

Michael S. Ramsey and Philip R. Christensen *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 34-36 (For primary document see N94-16595 03-42)

Avail: CASI HC A01/MF A01

Accurate interpretation of thermal infrared data depends upon the understanding and removal of complicating effects. These effects may include physical mixing of various mineralogies and particle sizes, atmospheric absorption and emission, surficial coatings, geometry effects, and differential surface temperatures. The focus is the examination of the linear spectral mixing of individual mineral or endmember spectra. Linear addition of spectra, for particles larger than the wavelength, allows for a straight-forward method of deconvolving the observed spectra, predicting a volume percent of each endmember. The 'forward analysis' of linear mixing (comparing the spectra of physical mixtures to numerical mixtures) has received much attention. The reverse approach of un-mixing thermal emission spectra was examined with remotely sensed data, but no laboratory verification exists. Understanding of the effects of spectral mixing on high resolution laboratory spectra allows for the extrapolation to lower resolution, and often more complicated, remotely gathered data. Thermal Infrared Multispectral Scanner (TIMS) data for Meteor Crater, Arizona were acquired in Sep. 1987. The spectral un-mixing of these data gives a unique test of the laboratory results. Meteor Crater (1.2 km in diameter and 180 m deep) is located in north-central Arizona, west of Canyon Diablo. The arid environment, paucity of vegetation, and low relief make the region ideal for remote data acquisition. Within the horizontal sedimentary sequence that forms the upper Colorado Plateau, the oldest unit sampled by the impact crater was the Permian Coconino Sandstone. A thin bed of the Toroweap Formation, also of Permian age, conformably overlays the Coconino. Above the Toroweap lies the Permian Kiabab Limestone which, in turn, is covered by a thin veneer of the Moenkopi Formation. The Moenkopi is Triassic in age and has two distinct sub-units in the vicinity of the crater. The lower Wupatki member is a fine-grained sandstone, while the upper Moqui member is a fissile siltstone. Ejecta from these units are preserved as inverted stratigraphy up to 2 crater radii from the rim. The mineralogical contrast between the units, relative lack of post-emplacement erosion and ejecta mixing provide a unique site to apply the un-mixing model. Selection of the aforementioned units as endmembers reveals distinct patterns in the ejecta of the crater. Author (revised)

THE USE OF TIMS DATA TO ESTIMATE THE SO2 CONCENTRATIONS OF VOLCANIC PLUMES: A CASE STUDY AT MOUNT ETNA, SICILY **c46**

Vincent J. Realmuto *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992

p 37-39 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

Thermal Infrared Multispectral Scanner (TIMS) data were acquired over Mount Etna, Sicily, on 29 July 1986. The volcanic activity at that time was characterized by the steady effusion of gas from the Bocca Nuova (BN), Chasm, and Southeast craters. The Northeast crater, quiet at the time of the TIMS overflight, was the site of Strombolian eruptive activity between 31 July and 24 Sep. 1986. In aerial photographs of the Etna summit region acquired during the TIMS overflight, the SO2-rich plume is visible due to the scattering of sunlight by the entrained aerosols. In the TIMS imagery, the plume is revealed by the strong absorption of SO2 between 8 and 9 microns. This absorption feature falls within the first three channels of TIMS, with the strongest absorption falling within Channel 2. Following decorrelation processing, the plume is visible in color-composites of TIMS channels 2, 3, and 5. To estimate the concentration of SO2 within the plume, the LOWTRAN 7 radiative transfer code was used to model the radiance spectra measured by TIMS. Author (revised)

IN-FLIGHT CALIBRATION OF THE SPECTRAL AND RADIOMETRIC CHARACTERISTICS OF AVIRIS IN 1991 **c35**
Robert O. Green, James E. Conel, Carol J. Bruegge, Jack S. Margolis, Veronique Carrere, Gregg Vane, and Gordon Hoover *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 1-4 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

On 7 Mar. 1991, an in-flight calibration experiment was held at the Ivanpah Playa in southeastern California for the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) imaging spectrometer. Five AVIRIS overflights were acquired of a calibration target designated on the Ivanpah Playa surface. At the time of the overflights, the reflectance of the calibration target was measured with a field spectrometer. In addition, the atmospheric optical depths and water vapor abundance were measured from a radiometer station adjacent to the calibration target. These in-situ measurements were used to constrain the MODTRAN radiative transfer code to model the upwelling spectral radiance incident to the sensor aperture during the overflights. Analyses of this modeled radiance in conjunction with the laboratory-calibrated radiance were used to determine the spectral and radiometric calibration of AVIRIS while in flight. Author (revised)

The Jasper Ridge Biological Preserve, Stanford, California is a good example of hardwood rangeland ecosystems in California. Structurally, it is composed of a mosaic of serpentine grasslands, oak savannah, coastal chaparral, and mixed evergreen woodland, representing a broad cross-section of physiognomic classes. The Mediterranean climate produces an extended seasonal drought lasting throughout most of the growing season and has significant impact on the expression of divergent phenological patterns related to contrasting ecological strategies of these taxa. The region is well understood biologically due to the rich history of ecological research at the site. Thus, community characteristics, physiological characteristics, phenology, and temporal dynamics are reasonably well understood for many of the dominant species. Because of its proximity to NASA Ames Research Center, it has been subject to a large number of aircraft data acquisitions over many years. A more complete examination of this database would provide an opportunity to test current remote sensing hypotheses for measurement and detection of ecological attributes, particularly those involving canopy chemistry and physiology. Better definition of ecological rules might permit development of remotely sensed surrogate variables for biological properties that cannot be directly measured or measured with sufficient accuracy. Five flight lines of Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data were acquired over the Dolly Varden Mountains in northeastern Nevada on 2 June 1989. Signal-to-noise ratio values are given. The empirical line method was used to convert AVIRIS radiance values to reflectance. This method involves calculating gain and offset values for each band. These values are based upon a comparison of the imaging spectrometer data and field reflectance measurements, both taken over the same ground targets. The targets used were a dark andesite flow and a bright playa. Author (revised)

The sedimentary sections exposed in the Canyonlands and Arches National Parks region of Utah (generally referred to as 'Canyonlands') consist of sandstones, shales, limestones, and conglomerates. Reflectance spectra of weathered surfaces of rocks from these areas show two components: (1) variations in spectrally detectable mineralogy, and (2) variations in the relative ratios of the absorption bands between minerals. Both types of information can be used together to map each major lithology and the Clark spectral features mapping algorithm is applied to do the job. Author (revised)

SPATIAL RESOLUTION AND CLOUD OPTICAL THICKNESS RETRIEVALS **c47**
Rand E. Feind, Sundar A. Christopher, and Ronald M. Welch *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 14-16 (For primary document see N94-16666 03-42)
(Contracts NAS5-30958; NAS5-30768; NAS5-31718)
Avail: CASI HC A01/MF A02

The impact of sensor spatial resolution and accurate cloud pixel identification on cloud property retrievals was investigated. Twelve fair weather cumulus (FWC) scenes of high spectral and spatial resolution Airborne Visible and Infrared Imaging Spectrometer (AVIRIS) data are analyzed. A variation of the 3-band ratio technique of Gao and Goetz is used to discriminate clouds from the background, and then a discrete

ordinate radiative transfer model is used to obtain optical thickness of cloudy regions for each scene. To study the effect of spatial resolution upon retrieved optical thickness, the 20 m AVIRIS data was spatially degraded to spatial resolutions ranging from 40 to 960 m. Cloud area, scene average optical thickness, and distribution of retrieved optical thickness are determined at each spatial resolution. Finally, a comparison between the 3-band ratio technique and monospectral reflectance thresholding, using 20 m spatial resolution data, is presented. Author (revised)

EVALUATION OF SPATIAL PRODUCTIVITY PATTERNS IN AN ANNUAL GRASSLAND DURING AN AVIRIS OVERFLIGHT **c43**
John A. Gamon, Christopher B. Field (Carnegie Institution of Washington, Stanford, CA.), and Susan L. Ustin (California Univ., Davis.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 17-19 Sponsored in part by A. W. Mellon Foundation (For primary document see N94-16666 03-42)
(CIW-Publ-1134) Avail: CASI HC A01/MF A02

In May 1991, coincident with an Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) overflight, a ground-based study covering 9 hectares of an annual grassland was completed. There were two goals of this ground study: (1) obtain ecologically and physiologically meaningful data for relating AVIRIS images to canopy structure, biochemistry, and physiology; and (2) evaluate the suitability of the 20-m AVIRIS pixel size for depicting detailed spatial patterns of productivity. HYPERSPECTRAL MODELING FOR EXTRACTING AEROSOLS FROM AIRCRAFT/SATELLITE DATA **c43**
G. Daniel Hickman and Michael J. Duggin (State Univ. of New York, Syracuse.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 20-22 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Sensitivity studies using the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) bands are currently under investigation. The objective of this research is to develop improved algorithms for the determination of aerosol type (e.g., presently described by S(sub 12). Preliminary computer calculations were made using LOWTRAN 7, which is the most advanced atmospheric code of the Air Force Geophysics Laboratory. LOWTRAN 7 permits the calculation of atmospheric transmission and absorption caused by aerosols and molecules along a non-homogeneous path for a variety of aerosol models. The calculations used the Navy Aerosol Model (NAM), which was constructed for the marine environment using a three component size distribution model. Calculations of the total transmittance (L(sub T)), the path radiance (L(sub P)), and the reflected radiance (L(sub r)) were made as a function of wavelength (lambda) from 0.4 to 2.4 microns for each of the 224 10 nm wide AVIRIS bands. These calculations were made for various types of atmospheres for the troposphere (0-2 km).

THE SPECTRAL IMAGE PROCESSING SYSTEM (SIPS): SOFTWARE FOR INTEGRATED ANALYSIS OF AVIRIS DATA **c43**
F. A. Kruse, A. B. Lefkoff, J. W. Boardman, K. B. Heidebrecht, A. T. Shapiro, P. J. Barloon, and A. F. H. Goetz *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 23-25 (For primary document see N94-16666 03-42)
(Contract NAS5-30552; NAGw-1601)
Avail: CASI HC A01/MF A02

The Spectral Image Processing System (SIPS) is a software package developed by the Center for the Study of Earth from Space (CSES) at the University of Colorado, Boulder, in response to a perceived need to provide integrated tools for analysis of imaging spectrometer data both spectrally and spatially. SIPS was specifically designed to deal with data from the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) and the High Resolution Imaging Spectrometer (HIRIS), but was tested with other datasets including the Geophysical and Environmental Research Imaging Spectrometer (GERIS), GEOSCAN images, and Landsat TM. SIPS was developed using the 'Interactive Data Language' (IDL). It takes advantage of high speed disk access and fast processors running under the UNIX operating system to provide rapid analysis of entire imaging spectrometer datasets. SIPS allows analysis of single or multiple imaging spectrometer data segments at full spatial and spectral resolution. It also allows visualization and interactive analysis of image cubes derived from quantitative analysis procedures such as absorption band characterization and spectral unmixing. SIPS consists of three modules: SIPS Utilities, SIPS—View, and SIPS Analysis. SIPS version 1.1 is described below. Author (revised)

Ultramafic rocks are relatively rare at the Earth's surface but constitute the vast majority of the Earth by volume. Exposures of ultramafic bodies are therefore crucial for deducing many important processes that occur in the Earth's mantle. An important science question regarding the spatial distribution, abundance, and composition of mafic minerals in ultramafic bodies that can be examined with advanced sensor data is the melting process. When a lherzolite melts, clinopyroxene (cpx) melts first and therefore variations in the modal amount of cpx remaining in the mantle are a reflection of the amount of fractional melting that has occurred. Fe goes preferentially into the melt during melting but a 20 percent batch melting (i.e. closed system) acquires less Fe relative to 20 percent fractional melting (i.e. open system). Since the strength and wavelength of diagnostic absorptions is a strong function of Fe content, it is possible to make maps of the variation in Fe:Mg ratios which can be related to the general melting process. Accurate ground-truth information about local mineralogy provides internal calibration and consistency checks. Investigations using imaging spectrometer are very complementary to field studies because advanced sensor data can provide a synoptic view of modal mineralogy and chemical composition whereas field studies focus on detailed characterization of local areas. Two excellent exposures of ultramafic lithologies are being investigated with visible to mid-infrared imaging spectrometer data: the Ronda peridotite near Ronda, Spain and the Beni Bousera ophiolitic fragment in northern Morocco. Although separated by the Alboran Sea, these bodies are thought to be related and represent fertile sub-continental mantle. The Ronda peridotite is predominantly spinel lherzolite but grades into harzburgite and shows considerable variation in major and trace element compositions. Mafic layering and dykes (i.e. olivine gabbro) are also observed. This indicates some sections of the peridotite have experienced greater degrees of partial melting. The Beni Bousera peridotite also contains mafic layers and dykes and grades into harzburgite representing similar fundamental shifts in the bulk chemistry of this ultramafic body probably related to an episode of partial melting. The specific mode of emplacement of these bodies is controversial and important for understanding the tectonic evolution of this region. Our investigations are not necessarily designed to help resolve this controversy. Rather, these exposures provide excellent and unusual examples of fertile mantle which have undergone variable degrees of partial melting. Author (revised)

AVIRIS STUDY OF DEATH VALLEY EVAPORITE DEPOSITS USING LEAST-SQUARES BAND-FITTING METHODS **c43**
J. K. Crowley and R. N. Clark (Geological Survey, Denver, CO.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 29-31 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Minerals found in playa evaporite deposits reflect the chemically diverse origins of ground waters in arid regions. Recently, it was discovered that many playa minerals exhibit diagnostic visible and near-infrared (0.4-2.5 micron) absorption bands that provide a remote sensing basis for observing important compositional details of desert ground water systems. The study of such systems is relevant to understanding solute acquisition, transport,

and fractionation processes that are active in the subsurface. Observations of playa evaporites may also be useful for monitoring the hydrologic response of desert basins to changing climatic conditions on regional and global scales. Ongoing work using Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data to map evaporite minerals in the Death Valley salt pan is described. The AVIRIS data point to differences in inflow water chemistry in different parts of the Death Valley playa system and have led to the discovery of at least two new North American mineral occurrences. Seven segments of AVIRIS data were acquired over Death Valley on 31 July 1990, and were calibrated to reflectance by using the spectrum of a uniform area of alluvium near the salt pan. The calibrated data were subsequently analyzed by using least-squares spectral band-fitting methods, first described by Clark and others. In the band-fitting procedure, AVIRIS spectra are fit compared over selected wavelength intervals to a series of library reference spectra. Output images showing the degree of fit, band depth, and fit times the band depth are generated for each reference spectrum. The reference spectra used in the study included laboratory data for 35 pure evaporite spectra extracted from the AVIRIS image cube. Additional details of the band-fitting technique are provided by Clark and others elsewhere in this volume. Author (revised)

'Shade' has a technical definition peculiar to linear spectral mixture analysis of imaging spectrometer data: it is the reduction in radiance from a surface due to lighting conditions and geometry, and includes topographic shading described by photometric functions as well as shadowing at all scales. 'Shade' is an important constituent of nearly all remotely sensed images, and is one endmember resolved in spectral mixture analysis, where it is represented as a fraction of the measured radiance and a characteristic spectrum. This spectrum is typically the null vector, provided the data have been corrected for atmospheric and instrument effects: i.e., 'shade' is the radiance from an ideal black surface. In topographic shading, irradiance is reduced - typically in proportion to cos(i), where i (incidence angle) is the angle between the sun and the local surface normal vectors. Therefore, the radiance is lowered by a multiplicative factor. Shadowing occurs when i is greater than 90 deg, or when sunlight is blocked by adjacent high terrain; the only irradiance is down-welling skylight and bounce light from adjacent terrain. In spectral mixture analysis, 'shade' is regarded as an additive term. In this regard, it is an accurate description of the proportion of a scene that consists of ideal shadows ('checkerboard mixing'); however, 'shade' represents the multiplicative cos(i) factor as well, as here it should be interpreted as the proportion of shadow that would darken the scene an equivalent amount. In either case, the 'shade' fraction is lessened by adjacency effects, because the scene has a non-zero reflectivity instead of the ideal black surface generally assumed. Author (revised)

Over the last decade, technological advances in airborne imaging spectrometers, having spectral resolution comparable with laboratory spectrometers, have made it possible to estimate biochemical constituents of vegetation canopies. Wessman estimated lignin concentration from data acquired with NASA's Airborne Imaging Spectrometer (AIS) over Blackhawk Island in Wisconsin. A stepwise linear regression technique was used to determine the single spectral channel or channels in the AIS data that best correlated with measured lignin contents using chemical methods. The regression technique does not take advantage of the spectral shape of the lignin reflectance feature as a diagnostic tool nor the increased discrimination among other leaf components with overlapping spectral features. A nonlinear least squares spectral matching technique was recently reported for deriving both the equivalent water thicknesses of surface vegetation and the amounts of water vapor in the atmosphere from contiguous spectra measured with the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS). The same technique was applied to a laboratory reflectance spectrum of fresh, green leaves. The result demonstrates that the fresh leaf spectrum in the 1.0-2.5 microns region consists of spectral components of dry leaves and the spectral component of liquid water. A linear least squares spectral matching technique for retrieving equivalent water thickness and biochemical components of green vegetation is described. Author

The primary objective of this research was to map as many spectrally distinct types of green vegetation (GV), non-photosynthetic vegetation (NPV), shade, and soil (endmembers) in an Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) scene as is warranted by the spectral variability of the data. Once determined, a secondary objective was to interpret these endmembers and their abundances spatially and spectrally in an ecological context. Author (revised)

VOLCANIC THERMAL FEATURES OBSERVED BY AVIRIS **c46**
Clive Oppenheimer (Open Univ., Milton, England.), David Pieri, Veronique Carrere, Michael Abrams (Open Univ., Milton, England.), David Rothery (Open Univ., Milton, England.), and Peter Francis (Open Univ., Milton, England.) *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 41-43 Sponsored by Natural Environmental Research Council (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

In July 1991, Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) was flown over Mount Etna and Stromboli, Italy. Lava-filled vents were then present within summit craters of both volcanoes. Since surfaces at magmatic temperatures radiate strongly over the wavelength ranges of the AVIRIS C- and D-spectrometers, it was hoped that the data collected would reveal clear thermal signatures, even of sub-pixel sized features, as have been observed in the 1.65 and 2.22 microns bands of Landsat Thematic Mapper images. This would provide an opportunity to explore the potential of imaging spectrometers for deriving temperature distributions of hot volcanic surfaces. Such research has implications for volcano monitoring in the EOS era, and also for any future AVIRIS deployments above active lava flows, lakes, and domes, where understanding of their behavior may be advanced by detailed thermal observations.

Avail: CASI HC A01/MF A02

The first steps of an experiment for investigating the capability of airborne spectrometer data for retrieval of biophysical parameters of vegetation, especially water conditions are presented. Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) and ISM data were acquired in the frame of the 1991 NASA/JPL and CNES campaigns on the Landes, South west France, a large and flat forest area with mainly maritime pines. In-situ measurements were completed at that time; i.e. reflectance spectra, atmospheric profiles, sampling for further laboratory analyses of elements

concentrations (lignin, water, cellulose, nitrogen,...). All information was integrated in an already existing data base (age, LAI, DBH, understory cover,...). A methodology was designed for (1) obtaining geometrically and atmospherically corrected reflectance data, (2) registering all available information, and (3) analyzing these multi-source informations. Our objective is to conduct comparative studies with simulation reflectance models, and to improve these models, especially in the MIR. Author (revised)

Mineral abundance maps of 18 minerals were made of the Cuprite Mining District using 1990 AVIRIS data and the Multiple Spectral Feature Mapping Algorithm (MSFMA) as discussed in Clark et al. This technique uses least-squares fitting between a scaled laboratory reference spectrum and ground calibrated AVIRIS data for each pixel. Multiple spectral features can be fitted for each mineral and an unlimited number of minerals can be mapped simultaneously. Quality of fit and depth from continuum numbers for each mineral are calculated for each pixel and the results displayed as a multicolor image. Author (revised)

SEASONAL AND SPATIAL VARIATIONS IN PHYTOPLANKTONIC CHLOROPHYLL IN EUTROPHIC MONO LAKE, CALIFORNIA, MEASURED WITH THE AIRBORNE VISIBLE AND INFRARED IMAGING SPECTROMETER (AVIRIS) **c43**
John M. Melack and Mary Gastil *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 53-55 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

The principal problem with application of airborne imaging spectrometers to lakes is the weak upwelling signal, especially when narrow spectral bands with high spatial resolution are sought. Furthermore, atmospheric path radiance dominates the signal received from dark targets such as lakes. Once atmospheric effects have been removed from the radiance received at the sensor, semi-empirical relationships can be developed to extract information about phytoplankton pigment concentrations for different underwater optical conditions. In lakes where concentrations of dissolved organics and suspended detritus may not co-vary with phytoplankton pigments, the many spectral channels of an imaging spectrometer such as AVIRIS are likely to be required to distinguish the various aquasols. The objectives of our study are to: (1) estimate the chlorophyll content of a lake with hundred-fold seasonal ranges in chlorophyll concentration using atmospherically corrected upwelling radiances derived from AVIRIS imagery, and (2) to examine spatial patterns in chlorophyll after reduction of the coherent noise in the imagery by filtering techniques. AVIRIS CALIBRATION AND APPLICATION IN COASTAL OCEANIC ENVIRONMENTS **c48**
Kendall L. Carder *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 58-59 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

The Airborne Visible-Infrared Imaging Spectrometer (AVIRIS) is a test-bed for future spacecraft sensors such as the High-Resolution Imaging Spectrometer and the Moderate-Resolution Imaging Spectrometers planned for the Earth Observing System. To use this sensor for ocean applications, S/N was increased by spatial averaging of images. Post-flight recalibration was accomplished using in situ the water-leaving radiance measured at flight time, modeling radiance transmission to the aircraft, and adding modeled atmospheric radiance to that value. The preflight calibration curve was then adjusted until aircraft and modeled total radiance values matched. Water-leaving radiance values from the recalibrated AVIRIS imagery were consistent with in situ data supporting the validity of the approach. Imagery of the absorption coefficient at 415 nm and backscattering coefficient at 671 nm were used to depict the dissolved and particulate constituents of an ebb-tidal esturance plume on the East coast of Florida. MAPPING VEGETATION TYPES WITH THE MULTIPLE SPECTRAL FEATURE MAPPING ALGORITHM IN BOTH EMISSION AND ABSORPTION **c43**
Roger N. Clark, Gregg A. Swayze, Christopher Koch, and Cathy Ager *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 60-62 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Vegetation covers a large portion of the Earth's land surface. Remotely sensing quantitative information from vegetation has proven difficult because in a broad sense, all vegetation is similar from a chemical viewpoint, and most healthy plants are green. Plant species are generally characterized by the leaf and flower or fruit morphology, not by remote sensing spectral signatures. But to the human eye, many plants show varying shades of green, so there is direct evidence for spectral differences between plant types. Quantifying these changes in a predictable manner has not been easy. The Clark spectral features mapping algorithm was applied to mapping spectral features in vegetation species. Author (revised)

MULTIPLE DATASET WATER-QUALITY ANALYSES IN THE VICINITY OF AN OCEAN WASTEWATER PLUME **c45**
Michael Hamilton, Curtiss O. Davis, W. Joseph Rhea, and Jeannette vandenBosch *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 63-65 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

The White's Point ocean outfall is the method of disposal for approximately 374 million gallons of treated wastewater per day from Los Angeles County. The photosynthetic characteristics and particle distributions have well-defined properties that can be exploited to yield information on transport of the plume, mixing dynamics, and resuspension of bottom sediments during periods of bottom current velocity in excess of ca. 0.1 m/s. This plume of particles serves as a conservative tracer, which was studied using a number of sampling platforms and strategies, including underway sawtooth, or 'tow-yo' sampling, moored arrays of instruments, stationary profiling, and now for the first time with remotely-sensed multispectral color imagery. Research in this area previously focused on examination of the plume as it relates to the local current field and transport of particles, and on the resuspension of bottom sediments during periods of increased currents. In addition, Wu et al elucidated techniques for separating the particle signal into photosynthetic and nonphotosynthetic components, based on the beam attenuation to chlorophyll fluorescence ratio. High-frequency time series measurements of the current field and bio-optical characteristics at a site close to the waste diffusers were also collected. These are being analyzed for the spectral characteristics of the longer-timescale variability, in order to predict particle transport through

simple meteorological measurements. With the advent of high spectral and spatial resolution imaging spectrometers such as AVIRIS, it is now possible to construct causal relationships between particle distributions and signature of the upwelled radiance from the surface. The availability of a constant and well-characterized source of material lends itself well to models which predict upwelled radiance from the surface. The availability of a constant and well-characterized source of material lends itself well to models which predict upwelled light as a function of particle distributions, photosynthetic pigments, colored dissolved organic material, and detrital and degradation products of photosynthesis. In addition, the spatial coverage provided by the tow-yo sampling device, combined with the profile measurements of the light field, should facilitate the best inverse modeling attempts possible thus far. MAC EUROPE 1991: EVALUATION OF AVIRIS, GER IMAGING SPECTROMETRY DATA FOR THE LAND APPLICATION TESTSITE OBERPFAFFENHOFEN **c43**

F. Lehmann, R. Richter, H. Rothfuss, K. Werner, P. Hausknecht, A. Mueller, and P. Strobl *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 66-68 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

During the MAC Europe 91 Campaign, the area of Oberpfaffenhofen including the land application testsite Oberpfaffenhofen was flown by the AVIRIS imaging spectrometer, the GER 2 imaging spectrometer (63 band scanner), and two SAR systems (NASA/JPL AIRSAR and DLR E-SAR). In parallel to the overflights ground spectrometry (ASD, IRIS M IV) and atmospheric measurements were carried out in order to provide data for optical sensor calibration. Ground spectrometry measurements were carried out in the runway area of the DLR research center Oberpfaffenhofen. This area was used as well during the GER 2 European flight campaign EISAC 89 as a calibration target. The land application testsite Oberpfaffenhofen is located 3 km north of the DLR research center. During the MAC Europe 91 Campaign a ground survey was carried out for documentation in the ground information data base (vegetation type, vegetation geometry, soil type, and soil mixture). Crop stands analyzed were corn, barley and rape. The DLR runway area and the land application testsite Oberpfaffenhofen were flown with the AVIRIS on 29 July and with the GER 2 on 12 and 23 July and 3 Sep. AVIRIS and GER 2 scenes were processed and atmospherically corrected for optical data analysis of optical and radar data. For the AVIRIS and the GER 2 scenes, signal-to-noise ratios (SNR) estimates were calculated. An example of the reflectance of 6 calibration targets inside a GER 2 scene of Oberpfaffenhofen is given. SNR values for the GER 2 for a medium albedo target are given. The integrated analysis for the optical and radar data was carried out in cooperation with the DLR Institute for Microwave Technologies. USING ENDMEMBERS IN AVIRIS IMAGES TO ESTIMATE CHANGES IN VEGETATIVE BIOMASS **c43**

Milton O. Smith, John B. Adams, Susan L. Ustin (California Univ., Davis.), and Dar A. Roberts *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 69-71 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

Field techniques for estimating vegetative biomass are labor intensive, and rarely are used to monitor changes in biomass over time. Remote-sensing offers an attractive alternative to field measurements; however, because there is no simple correspondence between encoded radiance in multispectral images and biomass, it is not possible to measure vegetative biomass directly from AVIRIS images. Ways to estimate vegetative biomass by identifying community types and then applying biomass scalars derived from field measurements are investigated. Field measurements of community-scale vegetative biomass can be made, at least for local areas, but it is not always possible to identify vegetation communities unambiguously using remote measurements and conventional image-processing techniques. Furthermore, even when communities are well characterized in a single image, it typically is difficult to assess the extent and nature of changes in a time series of images, owing to uncertainties introduced by variations in illumination geometry, atmospheric attenuation, and instrumental responses. Our objective is to develop an improved method based on spectral mixture analysis to characterize and identify vegetative communities, that can be applied to multi-temporal AVIRIS and other types of images. In previous studies, multi-temporal data sets (AVIRIS and TM) of Owens Valley, CA were analyzed and vegetation communities were defined in terms of fractions of reference (laboratory and field) endmember spectra. An advantage of converting an image to fractions of reference endmembers is that, although fractions in a given pixel may vary from image to image in a time series, the endmembers themselves typically are constant, thus providing a consistent frame of reference. ATMOSPHERIC CORRECTION OF AVIRIS DATA IN OCEAN WATERS **c48**

Gregory Terrie and Robert Arnone *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 72-74 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

Hyperspectral data offers unique capabilities for characterizing the ocean environment. The spectral characterization of the composition of ocean waters can be organized into biological and terrigenous components. Biological photosynthetic pigments in ocean waters have unique spectral ocean color signatures which can be associated with different biological species. Additionally, suspended sediment has different scattering coefficients which result in ocean color signatures. Measuring the spatial distributions of these components in the maritime environments provides important tools for understanding and monitoring the ocean environment. These tools have significant applications in pollution, carbon cycle, current and water mass detection, location of fronts and eddies, sewage discharge and fate etc. Ocean color was used from satellite for describing the spatial variability of chlorophyll, water clarity (K(sub 490)), suspended sediment concentration, currents etc. Additionally, with improved atmospheric correction methods, ocean color results produced global products of spectral water leaving radiance (L(sub W)). Ocean color results clearly indicated strong applications for characterizing the spatial and temporal variability of bio-optical oceanography. These studies were largely the results of advanced atmospheric correction techniques applied to multispectral imagery. The atmosphere contributes approximately 80 percent - 90 percent of the satellite received radiance in the blue-green portion of the spectrum. In deep ocean waters, maximum transmission of visible radiance is achieved at 490nm. Conversely, nearly all of the light is absorbed by the water at wavelengths greater than about 650nm and thus appears black. These spectral ocean properties are exploited by algorithms developed for the atmospheric correction used in satellite ocean color processing. The objective was to apply atmospheric correction techniques that were used for procesing satellite Coastal Zone Color Scanner (CZCS) data to AVIRIS data. Quantitative measures of L(sub W) from AVIRIS are compared with ship ground truth data and input into bio-optical models. Author (revised)

Airborne campaigns during the eighties provided high spectral resolution data, collected with imaging instruments such as AIS, AVIRIS, FLI, CAESI, and ISM, in order to investigate the relationship with canopy biophysical characteristics. The statistical approaches used to analyze these data do not allow investigation of the causality and the applicability of the observed correlations. Further, statistical studies demonstrated the high degree of

redundancy of the spectral information amongst many others. And for retrieving vegetation biophysical characteristics, few results demonstrate the real information gain attributable to the high spectral resolution capability as compared to the use of a few wide wavelength bands. With several new imaging spectrophotometers scheduled for launch during the next 10 years (MERIS, MODIS, HIRIS), progress in the description and understanding of the mechanisms that drive the spectral variation of canopy reflectance is required. Most of these new sensor systems will also have the capability to observe the target under differing view directions. The problem of the combination and the use of the synergy between both the spectral and the directional sources of canopy reflectance variations has to be addressed. Apart from the atmospheric effects, the spectral variation of the light reflected by canopies originates from the leaves, the soil or the other vegetation elements such as branches and fruits. At leaf level, both diffuse reflectance and transmittance may be simulated by simple models, although no accurate information exists on the absorption features of the biochemicals (except water) in the 900-2500nm wavelength range. Many models mimic the directional variability of canopy reflectance at a given wavelength. Combining a leaf spectral model with a canopy directional model provides a powerful tool to analyze this problem. Some of us have initiated such a study, but our approach and theory remain to be tested using canopy data with their complexity, associated experimental error, and atmospheric effects. The main objective of the 1990 POLDER/AVIRIS experiment in Camargue was to provide a consistent data set over various canopies in order to test the applicability of the theory. The experiment, part of the 1991 MAC Europe experiment, involved simultaneous data collection using two sensors: AVIRIS and POLDER which measures the bidirectional and polarization properties of the targets at 670 and 880nm wavebands. AVIRIS GROUND DATA PROCESSING SYSTEM **c43**
Earl G. Hansen, Steve Larson, H. Ian Novack, and Robert Bennett *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 80-82 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

During the last year and a half, Feb. 1991 to Jun. 1992, a major upgrade of the Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) ground data processing system took place. Both the hardware and software components were changed significantly to improve the processing capacity and performance and to structure a data facility capable of handling the projected work load into the near future. A summary report of these changes and some projections for the future are provided. The objectives of the AVIRIS data facility are to decommutate and archive AVIRIS data and to provide raw or radiometrically calibrated data products to the science investigator. These primary objectives have not changed from the initial concepts. The upgrade effort has greatly improved the processing system. These objectives can now be accomplished in a more timely fashion at a reasonable cost and there is sufficient capacity to manage the current processing load and provide for future growth. The method of implementation added the flexibility to provide better service to the investigator and allow for future changes. Author (revised)

The Advanced Thermal Emission and Reflectance Radiometer (ASTER) is a joint Japanese/US imaging instrument scheduled to fly on the first Earth Observing System (EOS) platform in 1998. The complement of scanners includes a visible, three channel module with forward-looking stereo capability, a six channel short wavelength infrared module, and a five channel thermal module. As part of the definition phase for the instrument design, AVIRIS data was used to simulate the short wave infrared (SWIR) bands to investigate the effects of widening two of the bands to increase the signal-to-noise ratio (SNR) versus loss of spectral separability due to uncertainty in the post-launch band positions. USE OF AVIRIS DATA TO THE DEFINITION OF OPTIMISED SPECIFICATIONS FOR LAND APPLICATIONS WITH FUTURE SPACEBORNE IMAGING SPECTROMETERS Abstract Only **c43**
J. Bodechtel *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 85 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Recent experience with airborne imaging spectrometers demonstrated the advantages of narrow band sensors over broad band scanners for characterizing the nature, extent, and physical status of typical land surfaces. Information on key spectral features associated with various land surfaces can be obtained from the data of such instruments, which can be used to simulate spaceborne imaging spectrometer data and to assess their information content if comprehensive underpinning is provided by ground data. The collection of such information was an issue of airborne imaging spectrometer campaigns like the NASA MAC-Europe 1991. Airborne and ground data obtained from different test sites in Europe are utilized for a comparative analysis of the spectral signatures of various land surfaces (vegetation, bare soils and rocks, and mixed soil/rock-vegetation) as seen from different imaging spectrometers like Airborne Visible/Infrared Imaging Spectrometer (AVIRIS), GERIS 63 band scanner, and CASI. The following items are discussed: (1) the significance of different spectral regions within the wavelength interval between 0.4 m and 2.5 m for the differentiation of different land units; (2) recommendations on the optimum band selection and band-widths to be used for the application of future satellite-based imaging spectrometers for land applications; (3) the boundaries for the detection of plant features in mixed-soil plant spectra and the influence of different soil properties on the mixture of the spectra; (4) recommendations on the optimum spatial resolution and recording dates for the discrimination of spectral features of various surface types; and (5) evaluation of different data compressing techniques for the optimum extraction of spectral information from imaging spectrometry data. Our primary results in Jasper Ridge Biological Preserve indicate that high spectral resolution Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data may provide a substantial advantage in vegetation, based on the chlorophyll red edge feature from 700-780 nm. The chlorophyll red edge was detected for green vegetation cover as low as 4.8 percent. The objective of our studies in Mono Lake area is to continue the experiments performed in Jasper Ridge and to examine the persistence of red edge feature of trace quantities of green vegetation for different plant communities with non-uniform soil backgrounds. JPL ACTIVITIES ON DEVELOPMENT OF ACOUSTO-OPTIC TUNABLE FILTER IMAGING SPECTROMETER **c35**
Li-Jen Cheng, Tien-Hsin Chao, and George Reyes *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 88-90 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Recent activities of JPL in the development of a new type of imaging spectrometers for earth observation and planetary exploration are reported. This instrument uses the acousto-optic tunable filter (AOTF) as high resolution and fast programmable bandpass filter. AOTF operates in the principle of acousto-optic interaction in an anisotropic medium. This filter can be tuned in sequential, random, and multiwavelength access modes, providing observational flexibility. The diffraction process in the filter generates two diffracted monochromatic beams with polarization orthogonal to each other, creating a unique capability to measure both polarimetric and spectral properties of the incoming light simultaneously with a single

instrument. The device gives wide wavelength operations with reasonably large throughput. In addition, it is in a compact solid-state structure without moving parts, providing system reliability. These attractive features give promising opportunities to develop a new generation of airborne/spaceborne and ground, real-time, imaging spectrometer systems for remote sensing applications. MEASURING DRY PLANT RESIDUES IN GRASSLANDS: A CASE STUDY USING AVIRIS **c43**

Michael Fitzgerald and Susan L. Ustin (California Univ., Davis.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 91-93 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

Grasslands, savannah, and hardwood rangelands are critical ecosystems and sensitive to disturbance. Approximately 20 percent of the Earth's surface are grasslands and represent 3 million ha. in California alone. Developing a methodology for estimating disturbance and the effects of cumulative impacts on grasslands and rangelands is needed to effectively monitor these ecosystems. Estimating the dry biomass residue remaining on rangelands at the end of the growing season provides a basis for evaluating the effectiveness of land management practices. The residual biomass is indicative of the grazing pressure and provides a measure of the system capacity for nutrient cycling since it represents the maximum organic matter available for decomposition, and finally, provides a measure of the erosion potential for the ecosystem. Remote sensing presents a possible method for measuring dry residue. However, current satellites have had limited application due to the coarse spatial scales (relative to the patch dynamics) and insensitivity of the spectral coverage to resolve dry plant material. Several hypotheses for measuring the biochemical constituents of dry plant material, particularly cellulose and lignin, using high spectral resolution sensors were proposed. The use of Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) to measure dry plant residues over an oak savannah on the eastern slopes of the Coast Range in central California was investigated and it was asked what spatial and spectral resolutions are needed to quantitatively measure dry plant biomass in this ecosystem. TRACKING PHOTOSYNTHETIC EFFICIENCY WITH NARROW-BAND SPECTRORADIOMETRY **c43**

John A. Gamon and Christopher B. Field (Carnegie Institution of Washington, Stanford, CA.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 95-97 Sponsored in part by A. W. Mellon Foundation (For primary document see N94-16666 03-42)

(CIW-Publ-1133) Avail: CASI HC A01/MF A02

Narrow-waveband spectroradiometry presents the possibility of detecting subtle signals closely related to the current physiological state of vegetation. One such signal related to the epoxidation state of the xanthophyll cycle pigments, violaxanthin, antheraxanthin, and zeaxanthin is discussed. Recent advances in plant ecophysiology demonstrated a close relationship between these pigments and the regulatory state of photosystem 2 in photosynthesis. Our recent field studies of sunflower (Helianthus annuus) and oak (Quercus agrifolia) demonstrated that a 'xanthophyll signal' can be isolated from the diurnal reflectance spectra of intact canopies. Furthermore, the xanthophyll signal can be used to derive a 'physiological reflectance index' (PRI) that closely correlates with the actual photosynthetic efficiency (defined as the photosynthetic rate divided by the incident PAR) in closed canopies. If these signals were detectable in Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) images, they could lead to improved remote estimates of photosynthetic fluxes. Author (revised)

SEPARATION OF CIRRUS CLOUD FROM CLEAR SURFACE FROM AVIRIS DATA USING THE 1.38 MICRON WATER VAPOR BAND **c47**

Bo-Cai Gao and Alexander F. H. Goetz *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 98-100 (For primary document see N94-16666 03-42)

(Contract NAS5-30552)

Avail: CASI HC A01/MF A02

Cirrus clouds play an important role in climate systems because of their large area coverage, persistence, and radiative effects. Thin cirrus clouds are difficult to detect in visible images and infrared images in the 10-12 micron atmospheric window region, particularly over land, because these clouds are partially transparent. Ackerman recently developed a method for detecting cirrus clouds using three narrow channels centered near 8, 11, and 12 microns, respectively, based on the analysis of IR emission spectra measured with a high spectral resolution interferometer. Barton also described a method for estimating cirrus cloud height and amount from measurements with two narrow channel radiometers of the Selective Chopper Radiometer on Nimbus 5. Both channels are located within the strong 2.7 micron water vapor band absorption region. One of the channels includes additional carbon dioxide absorption. A differential absorption technique with sets of empirical coefficients was used in the estimation of cirrus cloud heights and amounts. A technique using narrow channels in the strong 1.38 micron water vapor band absorption region for detecting cirrus clouds from spectral imaging data acquired by the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) on 5 Dec. 1991 during the FIRE (The First International Satellite Cloud Climatology Project (ISCCP) Regional Experiment) Phase 2 Field Experiment is described. INTEGRATING REMOTE SENSING TECHNIQUES AT CUPRITE, NEVADA: AVIRIS, THEMATIC MAPPER, AND FIELD SPECTROSCOPY **c43**

Bradley Hill, Greg Nash (Utah Univ., Salt Lake City.), Merrill Ridd (Utah Univ., Salt Lake City.), Phoebe L. Hauff (Spectral Research, Lafayette, CO.), and Phil Ebel (Earth Search Sciences, Inc., Salt Lake City, UT.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 104-107 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

The Cuprite mining district in southwestern Nevada has become a test site for remote sensing studies with numerous airborne scanners and ground sensor data sets collected over the past fifteen years. Structurally, the Cuprite region can be divided into two areas with slightly different alteration and mineralogy. These zones lie on either side of a postulated low-angle structural discontinuity that strikes nearly parallel to US Route 95. Hydrothermal alternation at Cuprite was classified into three major zones: silicified, opalized, and argillized. These alteration types form a bulls-eye pattern east of the highway and are more linear on the west side of the highway making a striking contrast from the air and the imagery. Cuprite is therefore an ideal location for remote sensing research as it exhibits easily identified hydrothermal zoning, is relatively devoid of vegetation, and contains a distinctive spectrally diagnostic mineral suite including the ammonium feldspar buddingtonite, several types of alunite, different jarosites, illite, kaolinite, smectite, dickite, and opal. This present study brings a new dimension to these previous remote sensing and ground data sets compiled for Cuprite. The development of a higher resolution field spectrometer now provides the capability to combine extensive in-situ mineralogical data with

a new geologic field survey and detailed Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) images. The various data collection methods and the refinement of the integrated techniques are discussed.

OREGON TRANSECT: COMPARISON OF LEAF-LEVEL REFLECTANCE WITH CANOPY-LEVEL AND MODELLED REFLECTANCE **c43**

Lee F. Johnson (TGS Technology, Inc., Moffett Field, CA.), Frederic Baret (Institut National de la Recherche Agronomique, Avignon, France.), and David L. Peterson *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 113-115 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

The Oregon Transect Ecosystem Research (OTTER) project involves the collection of a variety of remotely-sensed and in situ measurements for characterization of forest biophysical and biochemical parameters. The project includes nine study plots located along an environmental gradient in west-central Oregon, extending from the Pacific coast inland approximately 300km. These plots represent a broad range in ecosystem structure and function. Within the OTTER project, the sensitivity of the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) signal to absorption by foliar biochemicals is being examined. AVIRIS data were acquired over all plots in conjunction with the four OTTER Multi-sensor Aircraft Campaigns spanning the growing season. Foilage samples were gathered during each campaign for biochemical determination (at Ames Research Center), to estimate stand-level constituency at each plot. Directional-hemispheric leaf reflectance throughout the 400-2400nm region was measured in the laboratory as an aid to interpreting concurrent AVIRIS data. Obtaining leaf spectra in this manner reduces or eliminates the confounding influences of atmosphere, canopy architecture, and reflectance by woody components, understory, and exposed soils which are present in airborne observations. These laboratory spectra were compared to simulated spectra derived by inverting the PROSPECT leaf-level canopy reflectance derived from AVIRIS data by use of the LOWTRAN-7 atmospheric radiative-transfer model.

AVIRIS AS A TOOL FOR CARBONATITE EXPLORATION: COMPARISON OF SPAM AND MBANDMAP DATA ANALYSIS METHODS **c43**

Marguerite J. Kingston and James K. Crowley *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 116-118 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

Data acquired with the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) of the Mountain Pass, San Bernadino County, California, area were analyzed to evaluate the use of narrow-band imaging data for carbonatite exploration. Carbonatites are igneous carbonate-rich rocks that are economically important in part because they are the major source for rare-earth minerals. Because the 224 AVIRIS spectral channels have a nominal spectral resolution of 10 nm, narrow absorption features such as those displayed by the rare-earth elements neodymium (Nd) and samarium (Sm) may be detected. The Mountain Pass region encompasses a well-exposed sequence of sedimentary, metamorphic, and igneous rocks, including an alkalic carbonatite intrusion. The carbonatite was emplaced in Precambrian granitic rocks that are fault bounded by a thick suite of Paleozoic, sedimentary rock, predominantly dolomite. The carbonatite stock, the major source of light rare-earth elements (REE) in the United States, affords the opportunity to test AVIRIS capabilities for detecting REE absorption features. Nd-bearing minerals display narrow, sharp and distinctive spectral features at 580, 740, 800, and 870 nm. Minerals bearing Sm display similarly sharp features near 1090, 1250, 1410, and 1550 nm. The more common REE, lanthanum and cerium, do not display absorption features in the visible/near-infrared region in their natural oxidation states.

EXPERT SYSTEM-BASED MINERAL MAPPING USING AVIRIS **c43**

Fred A. Kruse, A. B. Lefkoff, and J. B. Dietz *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 119-121 Sponsored in part by Geological Survey (For primary document see N94-16666 03-42)

(Grants NAGw-1601; NAGw-1143)

Avail: CASI HC A01/MF A02

Integrated analysis of imaging spectrometer data and field spectral measurements were used in conjunction with conventional geologic field mapping to characterize bedrock and surficial geology at the northern end of Death Valley, California and Nevada. A knowledge-based expert system was used to automatically produce image maps from Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data showing the principal surface mineralogy. The imaging spectrometer data show the spatial distribution of spectrally distinct minerals occurring both as primary rock-forming minerals and as alteration and weathering products. Field spectral measurements were used to verify the mineral maps and field mapping was used to extend the remote sensing results. Geographically referenced image-maps produced from these data form new base maps from which to develop improved understanding of the processes of deposition and erosion affecting the present land surface. The 'northern Grapevine Mountains' (NGM) study area was reported on in numerous papers. This area is an unnamed northwestward extension of the range. Most of the research here has concentrated on mapping of Jurassic-age plutons and associated hydrothermal alteration, however, the nature and scope of these studies is much broader, pertaining to the geologic history and development of the entire Death Valley region. AVIRIS data for the NGM site were obtained during May 1989. Additional AVIRIS data were acquired during September 1989 as part of the Geologic Remote Sensing Field Experiment (GRSFE). The area covered by these data overlaps slightly with the May 1989 data. Three and one-half AVIRIS scenes total were analyzed. Author (revised)

AVIRIS DATA AND NEURAL NETWORKS APPLIED TO AN URBAN ECOSYSTEM **c63**

Merrill K. Ridd (Utah Univ., Salt Lake City.), Niles D. Ritter, Nevin A. Bryant, and Robert O. Green *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 129-131 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

Urbanization is expanding on every continent. Although urban/industrial areas occupy a small percentage of the total landscape of the earth, their influence extends far beyond their borders, affecting terrestrial, aquatic, and atmospheric systems globally. Yet little has been done to characterize urban ecosystems of their linkages to other systems horizontally or vertically. With remote sensing we now have the tools to characterize, monitor, and model urban landscapes world-wide. However, the remote sensing performed on cities so far has concentrated on land-use patterns as distinct from land-cover or composition. The popular Anderson system is entirely land-use oriented in urban areas. This paper begins with the premise that characterizing the biophysical composition of urban environments is fundamental to understanding urban/industrial ecosystems, and, in turn, supports the modeling of other systems interfacing with urban systems. Further, it is contended that remote sensing is a tool poised to provide the biophysical composition data to characterize urban landscapes.

TEMPORAL VARIATION IN SPECTRAL DETECTION THRESHOLDS OF SUBSTRATE AND VEGETATION IN AVIRIS IMAGES **c43**

Donald E. Sabol, Jr., Dar A. Roberts, Milton O. Smith, and John B. Adams *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 132-134 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

The ability to map changes over large surface areas over time is one of the advantages in using remote sensing as a monitoring tool. Temporal changes in the surface may be gradual, making them difficult to detect in the short-term, and because they commonly occur at the subpixel scale, they may be difficult to detect in the long-term as well. Also, subtle changes may be real or merely an artifact of image noise. It is, therefore, necessary to understand the factors that limit the detection of surface materials in evaluating temporal data. The spectral detectability of vegetation and soil

in the 1990 July and October Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data of Jasper Ridge, CA was evaluated and compared.

DISCUSSION OF BAND SELECTION AND METHODOLOGIES FOR THE ESTIMATION OF PRECIPITABLE WATER VAPOUR FROM AVIRIS DATA **c43**
Dena Schanzer and Karl Staenz (Canada Centre for Remote Sensing, Ottawa, Ontario.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 135-137 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

An Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data set acquired over Canal Flats, B.C., on 14 Aug. 1990, was used for the purpose of developing methodologies for surface reflectance retrieval using the 5S atmospheric code. A scene of Rogers Dry Lake, California (23 Jul. 1990), acquired within three weeks of the Canal Flats scene, was used as a potential reference for radiometric calibration purposes and for comparison with other studies using primarily LOWTRAN7. Previous attempts at surface reflectance retrieval indicated that reflectance values in the gaseous absorption bands had the poorest accuracy. Modifications to 5S to use 1 nm step size, in order to make fuller use of the 20 cm(sup -1) resolution of the gaseous absorption data, resulted in some improvement in the accuracy of the retrieved surface reflectance. Estimates of precipitable water vapor using non-linear least squares regression and simple ratioing techniques such as the CIBR (Continuum Interpolated Band Ratio) technique or the narrow/wide technique, which relate ratios of combinations of bands to precipitable water vapor through calibration curves, were found to vary widely. The estimates depended on the bands used for the estimation; none provided entirely satisfactory surface reflectance curves.

ABUNDANCE RECOVERY ERROR ANALYSIS USING SIMULATED AVIRIS DATA **c43**
William W. Stoner, Joseph C. Harsanyi, William H. Farrand, and Jennifer A. Wong *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 138-140 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Measurement noise and imperfect atmospheric correction translate directly into errors in the determination of the surficial abundance of materials from imaging spectrometer data. The effects of errors on abundance recovery were investigated previously using Monte Carlo simulation methods by Sabol et. al. The drawback of the Monte Carlo approach is that thousands of trials are needed to develop good statistics on the probable error in abundance recovery. This computational burden invariably limits the number of scenarios of interest that can practically be investigated. A more efficient approach is based on covariance analysis. The covariance analysis approach expresses errors in abundance as a function of noise in the spectral measurements and provides a closed form result eliminating the need for multiple trials. Monte Carlo simulation and covariance analysis are used to predict confidence limits for abundance recovery for a scenario which is modeled as being derived from Airborne Visible/Infrared Imaging Spectrometer (AVIRIS).

MULTITEMPORAL DIURNAL AVIRIS IMAGES OF A FORESTED ECOSYSTEM **c43**
Susan L. Ustin, Milton O. Smith (Washington Univ., Seattle.), and John B. Adams (Washington Univ., Seattle.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 141-143 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Both physiological and ecosystem structural information may be derived from diurnal images. Structural information may be inferred from changes in canopy shadows between images and from changes in spectral composition due to changes in proportions of subpixel mixing resulting from the differences in sun/view angles. Physiological processes having diurnal scales also may be measurable if a stable basis for spectral comparison can be established. Six diurnal images of an area east of Mt. Shasta, CA were acquired on 22 Sep. 1989. This unique diurnal data set provided an opportunity to test the consistency of endmember fractions and residuals. It was expected that shade endmember abundances would show the greatest change as lighting geometry changed and less change in the normalized fractional proportion of other endmembers. Diurnal changes in spectral features related to physiological characteristics may be identifiable as changes in wavelength specific residuals.

A COMPARISON OF LOWTRAN-7 CORRECTED AIRBORNE VISIBLE/INFRARED IMAGING SPECTROMETER (AVIRIS) DATA WITH GROUND SPECTRAL MEASUREMENTS **c43**
Peng-Yang Xu and Ronald Greeley *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 144-146 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Atmospheric correction of imaging spectroscopy data is required for quantitative analysis. Different models were proposed for atmospheric correction of these data. LOWTRAN-7 is a low-resolution model and computer code for predicting atmospheric transmittance and background radiance from 0 to 50,00 cm(sup -1) which was developed by the Air Force Geophysics Laboratory. The Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data used are radiometrically calibrated and include the 28 Sep. 1989 Providence Fan flight line segment 07, California. It includes a dark gravel surface defined as a calibration site by the Geologic Remote Sensing Field Experiment (GRSFE). Several ground measurements of portable spectrometer DAEDALUS AA440 Spectrafax were taken during the GRSFE, July 1989 field campaign. Comparisons of the LOWTRAN-7 corrected AVIRIS data with the ground spectrometer measuremont were made.

DISCRIMINATION AMONG SEMI-ARID LANDSCAPE ENDMEMBERS USING THE SPECTRAL ANGLE MAPPER (SAM) ALGORITHM **c43**
Roberta H. Yuhas, Alexander F. H. Goetz, and Joe W. Boardman (Commonwealth Scientific and Industrial Research Organization, North Ryde, Australia.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 147-149 (For primary document see N94-16666 03-42)
(Grant NAGw-270)
Avail: CASI HC A01/MF A02

Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) data were acquired during three consecutive seasons of the year (26 Sep. 1989, 22 Mar. 1990, and 7 Aug. 1990) over an area of the High Plains east of Greeley, Colorado. This region contains extensive eolian deposits in the form of stabilized dune complexes (small scale parabolic dunes superimposed on large scale longitudinal and parabolic dunes). Due to the dunes' large scale (2-10 km) and low relief (1-5 m), the scaling relationships that contribute to the evolution of this landscape are nearly impossible to understand without the use of remote sensing. Additionally, climate models indicate that the High Plains could be one of the first areas to experience changes in climate caused by either global warming or cooling. During the past 10,000 years there were at least three periods of extensive sand activity, followed by periods of landscape stability, as shown in the stratigraphic record of this area. Therefore, if the past is an indication of the future, the monitoring of this landscape and its sensitive ecosystem is important for early detection of regional and global climate change.

EMPIRICAL RELATIONSHIPS AMONG ATMOSPHERIC VARIABLES FROM RAWINSONDE AND FIELD DATA AS SURROGATES FOR AVIRIS MEASUREMENTS: ESTIMATION OF REGIONAL LAND SURFACE EVAPOTRANSPIRATION **c43**
James E. Conel, Gordon Hoover, Anne Nolin, Ron Alley, and Jack Margolis *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 150-151 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

Empirical relationships between variables are ways of securing estimates

of quantities difficult to measure by remote sensing methods. The use of empirical functions was explored between: (1) atmospheric column moisture abundance W (gm H2O/cm(sup 2) and surface absolute water vapor density rho(q-bar) (gm H2O/cm(sup 3), with rho density of moist air (gm/cm(sup 3), q-bar specific humidity (gm H2O/gm moist air), and (2) column abundance and surface moisture flux E (gm H2O/(cm(sup 2)sec)) to infer regional evapotranspiration from Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) water vapor mapping data. AVIRIS provides, via analysis of atmospheric water absorption features, estimates of column moisture abundance at very high mapping rate (at approximately 100 km(sup 2)/40 sec) over large areas at 20 m ground resolution. LOSSLESS COMPRESSION OF AVIRIS DATA: COMPARISON OF METHODS AND INSTRUMENT CONSTRAINTS **c43**

R. E. Roger, J. F. Arnold, M. C. Cavenor, and J. A. Richards *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 154-156 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

A family of lossless compression methods, allowing exact image reconstruction, are evaluated for compressing Airborne Visible/Infrared Imaging Spectrometers (AVIRIS) image data. The methods are used on Differential Pulse Code Modulation (DPCM). The compressed data have an entropy of order 6 bits/pixel. A theoretical model indicates that significantly better lossless compression is unlikely to be achieved because of limits caused by the noise in the AVIRIS channels. AVIRIS data differ from data produced by other visible/near-infrared sensors, such as LANDSAT-TM or SPOT, in several ways. Firstly, the data are recorded at a greater resolution (12 bits, though packed into 16-bit words). Secondly, the spectral channels are relatively narrow and provide continuous coverage of the spectrum so that the data in adjacent channels are generally highly correlated. Thirdly, the noise characteristics of the AVIRIS are defined by the channels' Noise Equivalent Radiances (NER's), and these NER's show that, at some wavelengths, the least significant 5 or 6 bits of data are essentially noise. SIMULATION OF AVHRR-K BAND RATIOS WITH AVIRIS **c43**

Melanie A. Wetzel and Ronald M. Welch (South Dakota School of Mines and Technology, Rapid City.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 157-159 (For primary document see N94-16666 03-42)

Avail: CASI HC A01/MF A02

The Advanced Very High Resolution Radiometer (AVHRR)-K polar-orbiting imager scheduled for launch by the mid-1990's will include two new near-infrared narrowband detectors, Band 3A, 1.58- 1.64 microns, and a modified (narrower) Band 2, 0.84-0.87 microns. The Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) is an ideal testbed for these bands. The results of a comparison between AVIRIS band ratio values and AVHRR-K radiances simulated from AVIRIS are summarized. Author (revised)

SUMMARIES OF THE THIRD ANNUAL JPL AIRBORNE GEOSCIENCE WORKSHOP. VOLUME 3: AIRSAR WORKSHOP

Jakob vanZyl, ed. 1 Jun. 1992 120 p Workshop held in Pasadena, CA, 1-5 Jun. 1992

(NASA-CR-194542; JPL-Publ-92-14-Vol-3; NAS 1.26:194542) Avail: CASI HC A06/MF A02

This publication contains the preliminary agenda and summaries for the Third Annual JPL Airborne Geoscience Workshop, held at the Jet Propulsion Laboratory, Pasadena, California, on 1-5 June 1992. This main workshop is divided into three smaller workshops as follows: (1) the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) workshop, on June 1 and 2; the summaries for this workshop appear in Volume 1; (2) the Thermal Infrared Multispectral Scanner (TIMS) workshop, on June 3; the summaries for this workshop appear in Volume 2; and (3) the Airborne Synthetic Aperture Radar (AIRSAR) workshop, on June 4 and 5; the summaries for this workshop appear in Volume 3. For individual titles, see N94-16732 through N94-16762.

A SNOW WETNESS RETRIEVAL ALGORITHM FOR SAR **c43**

Jian-Cheng Shi (California Univ., Santa Barbara.) and Jeff Dozier *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 1-3 (For primary document see N94-16731 03-42)

Avail: CASI HC A01/MF A02

The objectives of this study are: (1) to evaluate the backscattering signals response to snow wetness; and (2) to develop an algorithm for snow wetness measurement using C-band polarimetric synthetic aperture radar (SAR). In hydrological investigations, modeling and forecasting of snowmelt runoff requires information about snowpack properties and their spatial variability. In particular, timely measurement of snow parameters is needed for operational hydrology. The liquid water content of snowpack is one of the important parameters. Active microwave sensors are highly sensitive to liquid water in the snowpack because of the large dielectric contrast between ice and water in the microwave spectrum. They are not affected by weather and have a spatial resolution compatible with the topographic variation in alpine regions. However, a quantitative algorithm for retrieval snow wetness has not yet been developed. Author (revised)

COMPARISON OF JPL-AIRSAR AND DLR E-SAR IMAGES FROM THE MAC EUROPE 1991 CAMPAIGN OVER TESTSITE OBERPFAFFENHOFEN: FREQUENCY AND POLARIZATION DEPENDENT BACKSCATTER VARIATIONS FROM AGRICULTURAL FIELDS **c43**

C. Schmullius and J. Nithack *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 4-6 (For primary document see N94-16731 03-42)

Avail: CASI HC A01/MF A02

On July 12, the MAC Europe '91 (Multi-Sensor Airborne Campaign) took place over test site Oberpfaffenhofen. The DLR Institute of Radio-Frequency Technology participated with its C-VV, X-VV, and X-HH Experimental Synthetic Aperture Radar (E-SAR). The high resolution E-SAR images with a pixel size between 1 and 2 m and the polarimetric AIRSAR images were analyzed. Using both sensors in combination is a unique opportunity to evaluate SAR images in a frequency range from P- to X-band and to investigate polarimetric information. Author (revised)

MONITORING ENVIRONMENTAL STATE OF ALASKAN FORESTS WITH AIRSAR **c43**

Kyle C. McDonald, JoBea Way, Eric Rignot, Cindy Williams (Alaska Univ., Fairbanks.), Les Viereck (Alaska Univ., Fairbanks.), and Phylis Adams (Alaska Univ., Fairbanks.) *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 7-8 (For primary document see N94-16731 03-42)

Avail: CASI HC A01/MF A02

During March 1988 and May 1991, the JPL airborne synthetic aperture radar, AIRSAR, collected sets of multi-temporal imagery of the Bonanza Creek Experimental Forest near Fairbanks, Alaska. These data sets consist of series of multi-polarized images collected at P-, L-, and C-bands each over a period of a few days. The AIRSAR campaigns were complemented with extensive ground measurements that included observations of both static canopy characteristics such as forest architecture as well as properties that vary on short term time scales such as canopy dielectric conditions. Observations exist for several stands of deciduous and coniferous species including white spruce (Picea glauca), black spruce (Picea mariana), and balsam poplar (Populus balsamifera). Although the duration of each campaign was fairly short, significant changes in environmental conditions caused notable variations in the physiological state of the canopies. During the 1988 campaign, environmental conditions ranged from unseasonably warm to more normal subfreezing temperatures. This permitted AIRSAR observations of frozen and thawed canopy states. During May 1991, ice jams that occurred along the river caused many stands to flood while the subsequent clearing of the river then allowed the waters to recede, leaving a snow covered ground surface. This allowed observations of several stands during both flooded and nonflooded conditions. Furthermore, the local weather varied from clear sunny days to heavy overcast days with some

occurrence of rain. Measurements of leaf water potential indicated that this caused significant variations in canopy water status, allowing SAR observations of water stressed and unstressed trees. Mean backscatter from several stands is examined for the various canopy physiological states. The changes in canopy backscatter that occur as a function of environmental and physiological state are analyzed. Preliminary results of a backscatter signature modeling analysis are presented. The implications of using SAR to monitor canopy phenological state are addressed. Author (revised)

COMPARISON OF MODELED BACKSCATTER WITH SAR DATA AT P-BAND **c43**
Yong Wang, Frank W. Davis, and John M. Melack *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 9-11 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

In recent years several analytical models were developed to predict microwave scattering by trees and forest canopies. These models contribute to the understanding of radar backscatter over forested regions to the extent that they capture the basic interactions between microwave radiation and tree canopies, understories, and ground layers as functions of incidence angle, wavelength, and polarization. The Santa Barbara microwave model backscatter model for woodland (i.e. with discontinuous tree canopies) combines a single-tree backscatter model and a gap probability model. Comparison of model predictions with synthetic aperture radar (SAR) data and L-band (lambda = 0.235 m) is promising, but much work is still needed to test the validity of model predictions at other wavelengths. The validity of the model predictions at P-band (lambda = 0.68 m) for woodland stands at our Mt. Shasta test site was tested. Author (revised)

SAR BACKSCATTER FROM CONIFEROUS FOREST GAPS **c43**
John L. Day and Frank W. Davis *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 12-14 (For primary document see N94-16731 03-42)
(Contracts JPL-958468; CS-86-90)
Avail: CASI HC A01/MF A02

A study is in progress comparing Airborne Synthetic Aperture Radar (AIRSAR) backscatter from coniferous forest plots containing gaps to backscatter from adjacent gap-free plots. Issues discussed are how do gaps in the range of 400 to 1600 sq m (approximately 4-14 pixels at intermediate incidence angles) affect forest backscatter statistics and what incidence angles, wavelengths, and polarizations are most sensitive to forest gaps. In order to visualize the slant-range imaging of forest and gaps, a simple conceptual model is used. This strictly qualitative model has led us to hypothesize that forest radar returns at short wavelengths (eg., C-band) and large incidence angles (e.g., 50 deg) should be most affected by the presence of gaps, whereas returns at long wavelengths and small angles should be least affected. Preliminary analysis of 1989 AIRSAR data from forest near Mt. Shasta supports the hypothesis. Current forest backscatter models such as MIMICS and Santa Barbara Discontinuous Canopy Backscatter Model have in several cases correctly predicted backscatter from forest stands based on inputs of measured or estimated forest parameters. These models do not, however, predict within-stand SAR scene texture, or 'intrinsic scene variability' as Ulaby et al. has referred to it. For instance, the Santa Barbara model, which may be the most spatially coupled of the existing models, is not truly spatial. Tree locations within a simulated pixel are distributed according to a Poisson process, as they are in many natural forests, but tree size is unrelated to location, which is not the case in nature. Furthermore, since pixels of a simulated stand are generated independently in the Santa Barbara model, spatial processes larger than one pixel are not modeled. Using a different approach, Oliver modeled scene texture based on an hypothetical forest geometry. His simulated scenes do not agree well with SAR data, perhaps due to the simple geometric model used. Insofar as texture is the expression of biological forest processes, such as succession and disease, and physical ones, such as fire and wind-throw, it contains useful information about the forest, and has value in image interpretation and classification. Forest gaps are undoubtedly important contributors to scene variance. By studying the localized effects of gaps on forest backscatter, guided by our qualitative model, we hope to understand more clearly the manner in which spatial heterogeneities in forests produce variations in backscatter, which collectively give rise to scene texture. Avail: CASI HC A01/MF A02

The analysis of Jet Propulsion Laboratory (JPL) Airborne Synthetic Aperture Radar (AIRSAR) data over the Landes forest in South-West France revealed strong correlation between L- and especially P-band sigma degrees and the pine forest biomass. To explain the physical link of radar backscatter to biomass, a polarimetric backscattering model was developed and validated. Then the model was used in a simulation study to predict sigma degree sensitivity to undesired canopy and environmental parameters. Main results concerning the data analysis, modeling, and simulation at P-band are reported. Author (revised)

CHARACTERIZATION OF WETLAND, FOREST, AND AGRICULTURAL ECOSYSTEMS IN BELIZE WITH AIRBORNE RADAR (AIRSAR) **c43**
Kevin O. Pope, Jose Maria Rey-Benayas, and Jack F. Paris (California State Univ., Fresno.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 18-20 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

The Shuttle Imaging Radar-C/X-SAR (Synthetic Aperture Radar) Experiment includes the study of wetland dynamics in the seasonal tropics. In preparation for these wetland studies, airborne P, L, and C band radar (AIRSAR) data of Belize, Guatemala, and Mexico acquired by NASA and JPL in March 1990 were analyzed. The first phase of our study focuses on AIRSAR data from the Gallon Jug test site in northwestern Belize, for which ground data were also collected during the three days prior to the overflight. One of the main objectives of the Gallon Jug study is to develop a method for characterizing wetland vegetation types and their flooding status with multifrequency polarimetric radar data. STRATEGIES FOR DETECTION OF FLOODPLAIN INUNDATION WITH MULTI-FREQUENCY POLARIMETRIC SAR **c43**
Laura L. Hess and John M. Melack *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 21-23 (For primary document see N94-16731 03-42)
(Contract JPL-958469)
Avail: CASI HC A01/MF A02

Mapping of floodplain inundation patterns is a key element in developing hydrological and biogeochemical models for large tropical river basins such as the Amazon. Knowledge of the time sequence of inundation is necessary to determine both water routing and biogenic gas fluxes. Synthetic Aperture Radar (SAR) is uniquely suited for this application because of its ability to penetrate cloud cover and, in many cases, to detect flooding beneath a forest or herbaceous canopy. A procedure for discriminating flooded forest, flooded herbaceous vegetation, and open water from other cover types for a coastal wetland site on the lower Altamaha floodplain, Georgia, emphasizing robust classifiers that are not site-specific is currently being developed. SUPERVISED FULLY POLARIMETRIC CLASSIFICATION OF THE BLACK FOREST TEST SITE: FROM MAESTROI TO MAC EUROPE **c43**
G. DeGrandi, C. Lavalle, H. DeGroof, and A. Sieber *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 24-26 (For primary document see N94-16731

03-42)
Avail: CASI HC A01/MF A02

A study on the performance of a supervised fully polarimetric maximum likelihood classifier for synthetic aperture radar (SAR) data when applied to a specific classification context: forest classification based on age classes and in the presence of a sloping terrain is presented. For the experimental part, the polarimetric AIRSAR data at P, L, and C-band, acquired over the German Black Forest near Freiburg in the frame of the 1989 MAESTRO-1 campaign and the 1991 MAC Europe campaign was used, MAESTRO-1 with an ESA/JRC sponsored campaign, and MAC Europe (Multi-sensor Aircraft Campaign); in both cases the multi-frequency polarimetric JPL Airborne Synthetic Aperture Radar (AIRSAR) radar was flown over a number of European test sites. The study is structured as follows. At first, the general characteristics of the classifier and the dependencies from some parameters, like frequency bands, feature vector, calibration, using test areas lying on a flat terrain are investigated. Once it is determined the optimal conditions for the classifier performance, we then move on to the study of the slope effect. The bulk of this work is performed using the Maestrol data set. Next the classifier performance with the MAC Europe data is considered. The study is divided into two stages: first some of the tests done on the Maestro data are repeated, to highlight the improvements due to the new processing scheme that delivers 16 look data. Second we experiment with multi images classification with two goals: to assess the possibility of using a training set measured from one image to classify areas in different images; and to classify areas on critical slopes using different viewing angles. The main points of the study are listed and some of the results obtained so far are highlighted. Author (revised)

RELATING MULTIFREQUENCY RADAR BACKSCATTERING TO FOREST BIOMASS: MODELING AND AIRSAR MEASUREMENT **c43**
Guo-Qing Sun (Ressler Associates, Inc., Laurel, MD.) and K. Jon Ranson *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 27-29 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

During the last several years, significant efforts in microwave remote sensing were devoted to relating forest parameters to radar backscattering coefficients. These and other studies showed that in most cases, the longer wavelength (i.e. P band) and cross-polarization (HV) backscattering had higher sensitivity and better correlation to forest biomass. This research examines this relationship in a northern forest area through both backscatter modeling and synthetic aperture radar (SAR) data analysis. The field measurements were used to estimate stand biomass from forest weight tables. The backscatter model described by Sun et al. was modified to simulate the backscattering coefficients with respect to stand biomass. The average number of trees per square meter or radar resolution cell, and the average tree height or diameter breast height (dbh) in the forest stand are the driving parameters of the model. The rest of the soil surface, orientation, and size distributions of leaves and branches, remain unchanged in the simulations. Author (revised)

SAR OBSERVATIONS IN THE GULF OF MEXICO **c43**
David Sheres *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 30-31 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

The Gulf of Mexico (GOM) exhibits a wealth of energetic ocean features; they include the Loop Current with velocities of about 2 m/s and strong shear fronts, mesoscale eddies, double vortices, internal waves, and the outflow of the 'Mighty Mississippi' river. These energetic features can have a strong impact on the economies of the states surrounding the Gulf. Large fisheries, oil and gas production as well as pollution transport are relevant issues. These circulation features in the Gulf are invisible to conventional IR and visible satellite imagery during the Summer months due to cloud cover and uniform surface temperatures. Synthetic Aperture Radar (SAR) imagery of the Gulf does penetrate the cloud cover and shows a rich assembly of features there year-round. Below are preliminary results from GOM SAR imagery taken by SEASAT in 1978 and by the AIRSAR program in 1991. Author (revised)

MAPPING OF SEA BOTTOM TOPOGRAPHY **c48**
C. J. Calkoen, G. J. Wensink, and G. H. F. M. Hesselmans *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 35-37 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Under suitable conditions the bottom topography of shallow seas is visible in remote sensing radar imagery. Two experiments were performed to establish which remote sensing technique or combination yields optimal imaging of bottom topography and which hydro-meteorological conditions are favorable. A further goal is to gain experience with these techniques. Two experiments were performed over an area in the North Sea near the measuring platform Meetpost Noordwijk (MPN). The bottom topography in the test area is dominated by sand waves. The crests of the sand waves are perpendicular to the coast line and the dominating (tidal-)current direction. A 4x4 sq km wide section of the test area was studied in more detail. The first experiment was undertaken on 16 Aug. 1989. During the experiment the following remote sensing instruments were used: Landsat-Thematic Mapper, and NASA/JPL Airborne Imaging Radar (AIR). The hydro-meteorological conditions; current, wind, wave, and air and water temperature were monitored by MPN, a ship of Rijkswaterstaat (the OCTANS), and a pitch-and-roll WAVEC-buoy. The second experiment took place on 12 July 1992. During this experiment data were collected with the NASA/JPL polarimetric synthetic aperture radar (SAR), and a five-band helicopter-borne scatterometer. Again the hydro-meteorological conditions were monitored at MPN and the OCTANS. Furthermore, interferometric radar data were collected. Author (revised)

SEA BOTTOM TOPOGRAPHY IMAGING WITH SAR **c48**
M. W. A. vanderKooij, G. J. Wensink (Delft Hydraulics Lab., Emmeloord, Netherlands.), and J. Vogelzang (Rijkswaterstaat, Delft, Netherlands.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 38-39 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

It is well known that under favorable meteorological and hydrodynamical conditions the bottom topography of shallow seas can be mapped with airborne or spaceborne imaging radar. This phenomenon was observed for the first time in 1969 by de Loor and co-workers in Q-band Side Looking Airborne Radar (SLAR) imagery of sandwaves in the North Sea. It is now generally accepted that the imaging mechanism consists of three steps: (1) interaction between (tidal) current and bottom topography causes spatial modulations in the surface current velocity; (2) modulations in the surface current velocity give rise to variations in the spectrum of wind-generated waves, as described by the action balance equation; and (3) variations in the wave spectrum show up as intensity modulations in radar imagery. In order to predict radar backscatter modulations caused by sandwaves, an imaging model, covering the three steps, was developed by the Dutch Sea

Bottom Topography Group. This model and some model results will be shown. On 16 Aug. 1989 an experiment was performed with the polarimetric P-, L-, and C-band synthetic aperture radar (SAR) of NASA/JPL. One scene was recorded in SAR mode. On 12 Jul. 1991 another three scenes were recorded, of which one was in the ATI-mode (Along-Track Interferometer). These experiments took place in the test area of the Sea Bottom Topography Group, 30 km off the Dutch coast, where the bottom topography is dominated by sand waves. In-situ data were gathered by a ship in the test area and on 'Measuring Platform Noordwijk', 20 km from the center of the test area. The radar images made during the experiment were compared with digitized maps of the bottom. Furthermore, the profiles of radar backscatter modulation were compared with the results of the model. During the workshop some preliminary results of the ATI measurements will be shown. Author (revised)

PRELIMINARY RESULTS OF POLARIZATION SIGNATURES FOR GLACIAL MORAINES IN THE MONO BASIN, EASTERN SIERRA NEVADA **c46**
Richard R. Forster, Andrew N. Fox, and Bryan Isacks *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 40-42 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

The valleys of the Mono Basin contain several sets of lateral and terminal moraines representing multiple stages of glaciation. The semi-arid climate with slow weathering rates preserved sequences of nested younger moraines within older ones. There is a well established relative chronology and recently exposure dating provided a new set of numerical dates. The moraines span the late Wisconsin (11-25 ka) to the Illinoian (130-190 ka) glaciations. The Mono Basin area was used as a 'calibration site' to establish remote dating techniques for eventual transfer to the more inaccessible but geomorphically and climatically similar moraines of the South American Andes Mountains. Planned polarimetric synthetic aperture radar (SAR) imagery acquired by JPL AIRSAR (South American Campaign) and SIR-C (Andes super-site) are analyzed to establish chronologies of previously undated moraine sequences in a study of Pleistocene climatic change in the Southern Hemisphere. The dry climate and sparse vegetation is also favorable for correlation of ground surface roughness with radar polarization signature. The slow weathering processes acting over thousands of years reduce the size, frequency, and angularity of surface boulders while increasing soil development on the moraines. Field observations based on this hypothesis result in relative ages consistent with those inferred from nested position within the valley. Younger moraines, therefore, will appear rougher than the older smoother moraines at scales measurable at AIRSAR wavelengths. Previously documented effects of ground surface roughness on polarization signatures suggest that analysis of moraine polarization signatures can be useful for relative dating. The technique may be extended to predict numerical ages. The data set reported were acquired on 8 Sep. 1989 with the JPL Airborne SAR (AIRSAR) collecting polarimetric imagery at C- (5.6 cm), L- (24 cm), and P-band (68 cm) with a flight-line parallel to the strike of the mountains. Phase calibration was performed on the analyzed scene by setting the co-phase of a smooth lake to zero as described. Absolute amplitude calibration was not possible because corner reflectors were not deployed. Author (revised)

DETECTING SURFACE ROUGHNESS EFFECTS ON THE ATMOSPHERIC BOUNDARY LAYER VIA AIRSAR DATA: A FIELD EXPERIMENT IN DEATH VALLEY, CALIFORNIA **c46**
Dan G. Blumberg and Ronald Greeley *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 43-45 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

The part of the troposphere influenced by the surface of the earth is termed the atmospheric boundary layer. Flow within this layer is influenced by the roughness of the surface; rougher surfaces induce more turbulence than smoother surfaces and, hence, higher atmospheric transfer rates across the surface. Roughness elements also shield erodible particles, thus decreasing the transport of windblown particles. Therefore, the aerodynamic roughness length (z(sub 0)) is an important parameter in aeolian and atmospheric boundary layer processes as it describes the aerodynamic properties of the underlying surface. z(sub 0) is assumed to be independent of wind velocity or height, and dependent only on the surface topography. It is determined using in situ measurements of the wind speed distribution as a function of height. For dry, unvegetated soils the intensity of the radar backscatter (sigma(sup 0)) is affected primarily by surface roughness at a scale comparable with the radar wavelength. Thus, both wind and radar respond to surface roughness variations on a scale of a few meters or less. Greeley showed the existence of a correlation between z(sub 0) and sigma(sup 0). This correlation was based on measurements over lava flows, alluvial fans, and playas in the southwest deserts of the United States. It is shown that the two parameters behave similarly also when there are small changes over a relatively homogeneous surface.

Polarimetric Airborne Synthetic Aperture Radar (AIRSAR) data were collected for the Geologic Remote Sensing Field Experiment (GRSFE) over Death Valley, California, USA, in Sep. 1989. AIRSAR is a four-look, quad-polarization, three frequency instrument. It collects measurements at C-band (5.66 cm), L-band (23.98 cm), and P-band (68.13 cm), and has a GIFOV of 10 meters and a swath width of 12 kilometers. Because the radar measures at three wavelengths, different scales of surface roughness are measured. Also, dielectric constants can be calculated from the data. The AIRSAR data were calibrated using in-scene trihedral corner reflectors to remove cross-talk; and to calibrate the phase, amplitude, and co-channel gain imbalance. The calibration allows for the extraction of accurate values of rms surface roughness, dielectric constants, sigma(sub 0) backscatter, and polarization information. The radar data sets allow quantitative characterization of small scale surface structure of geologic units, providing information about the physical and chemical processes that control the surface morphology. Combining the quantitative information extracted from the radar data with other remotely sensed data sets allows discrimination, identification and mapping of geologic units that may be difficult to discern using conventional techniques. Avail: CASI HC A01/MF A02

The NASA DC-8 AIRSAR instrument was augmented with a pair of C-band antennas displaced across track to form an interferometer sensitive to topographic variations of the Earth's surface. The antennas were developed by the Italian consortium Co.Ri.S.T.A., under contract to the Italian Space Agency (ASI), while the AIRSAR instrument and modifications to it supporting TOPSAR were sponsored by NASA. A new data processor was developed at JPL for producing the topographic maps, and a second processor was developed at Co.Ri.S.T.A. All the results presented below were processed at JPL. During the 1991 DC-8 flight campaign, data were acquired over several sites in the United States and Europe, and topographic maps were produced from several of these flight lines. Analysis of the results indicate that statistical errors are in the 2-3 m range for flat terrain and in the 4-5 m range for mountainous areas. Author (revised)

FITTING A THREE-COMPONENT SCATTERING MODEL TO POLARIMETRIC SAR DATA **c43**
A. Freeman and S. Durden *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 56-58 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

A new technique for fitting a three-component scattering mechanism model to the polarimetric synthetic aperture radar (SAR) data itself, without utilizing any ground truth measurements, is presented. The three scattering mechanism components included in the model are volume scatter from randomly oriented dipoles, first-order Bragg surface scatter and a dihedral scattering mechanism for two surfaces with different dielectric constants. The model fit yields an estimate of the contribution to the total backscatter of each of the three components. The backscatter contributions can also be compared to give the relative percentage weight of each. The model fit has an equal number of input parameters (the polarimetric radar backscatter measurements) and output parameters (the backscatter parameters describing them). The model can be applied to entire images or to small areas within an image to give a first-order estimate of the relevant scattering mechanisms. The model was applied to many C-, L- and P-band Airborne SAR (AIRSAR) images of different types of terrain. Results were presented at the workshop. Author (revised)

APPLICATION OF SYMMETRY PROPERTIES TO POLARIMETRIC REMOTE SENSING WITH JPL AIRSAR DATA **c43**
S. V. Nghiem, Simon H. Yueh, R. Kwok, and F. K. Li *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 59-61 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Based on symmetry properties, polarimetric remote sensing of geophysical media is studied. From the viewpoint of symmetry groups, media with reflection, rotation, azimuthal, and centrical symmetries are considered. The symmetries impose relations among polarimetric scattering coefficients, which are valid to all scattering mechanisms in the symmetrical configurations. Various orientation distributions of non-spherical scatterers can be identified from the scattering coefficients by a comparison with the symmetry calculations. Experimental observations are then analyzed for many geophysical scenes acquired with the Jet Propulsion Laboratory (JPL) airborne polarimetric SAR at microwave frequencies over sea ice and vegetation. Polarimetric characteristics of different ice types are compared with symmetry behaviors. The polarimetric response of a tropical rain forest reveals characteristics close to the centrical symmetry properties, which can be used as a distributed target to relatively calibrate polarimetric radars without any deployment of manmade calibration targets. EXTERNAL CALIBRATION OF POLARIMETRIC RADAR IMAGES USING DISTRIBUTED TARGETS **c43**
Simon H. Yueh, S. V. Nghiem, and R. Kwok *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 62-64 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

A new technique is presented for calibrating polarimetric synthetic aperture radar (SAR) images using only the responses from natural distributed targets. The model for polarimetric radars is assumed to be X = cRST where X is the measured scattering matrix corresponding to the target scattering matrix S distorted by the system matrices T and R (in general T does not equal R(sup t)). To allow for the polarimetric calibration using only distributed targets and corner reflectors, van Zyl assumed a reciprocal polarimetric radar model with T = R(sup t); when applied for JPL SAR data, a heuristic symmetrization procedure is used by POLCAL to compensate the phase difference between the measured HV and VH responses and then take the average of both. This heuristic approach causes some non-removable cross-polarization responses for corner reflectors, which can be avoided by a rigorous symmetrization method based on reciprocity. After the radar is made reciprocal, a new algorithm based on the responses from distributed targets with reflection symmetry is developed to estimate the cross-talk parameters. The new algorithm never experiences problems in convergence and is also found to converge faster than the existing routines implemented for POLCAL. When the new technique is implemented for the JPL polarimetric data, symmetrization and cross-talk removal are performed on a line-by-line (azimuth) basis. After the cross-talks are removed from the entire image, phase and amplitude calibrations are carried out by selecting distributed targets either with azimuthal symmetry along the looking direction or with some well-known volume and surface scattering mechanisms to estimate the relative phases and amplitude responses of the horizontal and vertical channels.

Microwave remote sensing technique has a high potential for measuring soil moisture due to the large contrast in dielectric constant of dry and wet soils. Recent work by Pults et al. demonstrated the use of X/C-band data for quantitative surface soil moisture extraction from Airborne Synthetic Aperture Radar (SAR) system. Similar technique was adopted using polarimetric SAR data acquired with the JPL-AIRSAR system over the Mahantango watershed area in central Pennsylvania during July 1990. The data sets reported include C-, L-, and P-bands of 10, 13, 15, and 17 July 1990. Author (revised)

Engman *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 69-71 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Results of ongoing efforts to develop an algorithm for soil moisture retrieval from Synthetic Aperture Radar (SAR) imagery are reported. Estimates of soil moisture are of great importance in numerous environmental studies, including hydrology, meteorology, and agriculture. Previous studies using extensive scatterometer measurements have established the optimum parameters for moisture retrieval as C-band HH radar operating at incidence angles between 10 to 15 deg. However, these parameters were not tested or verified with imaging radar systems. The results from different investigators showed considerable variability in the relationship between soil moisture and radar backscattering. This variability suggests that those algorithms are site-specific. Furthermore, the small incidence angle requirement limits the spatial application, especially for airborne radar systems.

INTERACTION TYPES AND THEIR LIKE-POLARIZATION PHASE-ANGLE DIFFERENCE SIGNATURES **c43**
Jack F. Paris *In* JPL, Summaries of the Third Annual JPL Airborne

Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 72-74 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

The JPL Airborne Synthetic Aperture Radar (AIRSAR) measures the full polarimetric properties of scene objects. AIRSAR data contain a complete set of magnitudes (for all linearly-polarized combinations (viz., VV, HH, and CS (cross Polarization))) and phase-angle differences (for all pairs of linearly-polarized components) for each image pixel. Radar images users have been greatly interested in the like-polarization (LK) phase-angle difference parameter, delta phi(sub LK). Usually, it is associated with the type of interaction between microwaves and scene-object scattering-elements. One value of delta phi(sub LK) is said to be produced by a dominant single scattering (or reflection) event, and another value is said to be the result of a dominant double-scattering (or double reflection) event. these are often called 'single bounce' and 'double bounce' interaction signatures, respectively. There appears to be a significant amount of confusion about how the interaction processes produce the characteristic values of delta phi(sub LK) and about what value of delta phi(sub LK) should be associated with each specific type. This issue is addressed.

Avail: CASI HC A01/MF A02

Three overflights of the Flevoland calibration/agricultural site were made by the JPL Airborne Synthetic Aperture Radar (AIRSAR) on 3, 12, and 28 July 1991 as part of MAC-Europe '92. A polygon map was generated at TNO-FEL which overlayed the slant range projected July 3 data set. Each polygon was identified by a sequence of points and a crop label. The polygon map was composed of 452 uniquely identified polygons and 15 different crop types. Analysis of the data was done using our modified Video Image Communication and Retrieval/Image Based Information System Geographic Information System (VICAR/IBIS GIS). This GIS is an extension of the VICAR/IBIS GIS first developed by Bryant in the 1970's which is itself an extension of the VICAR image processing system also developed at JPL.

Imaging radar data provides information about the geometric and dielectric properties of the Earth's surface. The Jet Propulsion Laboratory (JPL) polarimetric Airborne Synthetic Aperture Radar (AIRSAR) is currently obtaining imaging radar data for use in geologic, vegetation, snow and ice, and ocean studies. In the near future, the Shuttle Imaging Radar C (SIR-C/X-SAR) and the Earth Observing System Synthetic Aperture Radar (EOS SAR) will also collect polarimetric radar data. A need exists for a user-friendly, interactive software package for analysis of these polarimetric radar data sets. Previous software packages, such as JPL's Multiview, while providing some analysis capabilities for these data, did not allow interactive viewing and were tied to specific image display hardware with operating system dependencies. A prototype software system, the 'Radar Analysis and Visualization Environment' (RAVEN) under development at the Center for the Study of Earth from Space (CSES) at the University of Colorado, is designed to deal with data from the JPL AIRSAR instrument and other proposed polarimetric radar instruments. RAVEN is being developed using the Interactive Data Language (IDL). It takes advantage of high speed disk access and fast processors running under the UNIX operating system in an X-windows environment to allow for rapid, interactive visualization of AIRSAR data in both image and graphical ways. It provides a user-friendly interface through the use of menus, sliders, buttons, and display windows.

SOIL CONSERVATION APPLICATIONS WITH C-BAND SAR **c48**
B. Brisco, R. J. Brown (Canada Centre for Remote Sensing, Ottawa, Ontario.), J. Naunheimer, and D. Bedard *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 86-88 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Soil conservation programs are becoming more important as the growing human population exerts greater pressure on this non-renewable resource. Indeed, soil degradation affects approximately 10 percent of Canada's agricultural land with an estimated loss of 6,000 hectares of topsoil annually from Ontario farmland alone. Soil loss not only affects agricultural productivity but also decreases water quality and can lead to siltation problems. Thus, there is a growing demand for soil conservation programs and a need to develop an effective monitoring system. Topography and soil type information can easily be handled within a geographic information system (GIS). Information about vegetative cover type and surface roughness, which both experience considerable temporal change, can be obtained from remote sensing techniques. For further development of the technology to produce an operational soil conservation monitoring system, an experiment was conducted in Oxford County, Ontario which investigated the separability of fall surface cover type using C-band Synthetic Aperture Radar (SAR) data.

COMPARISON OF EDGES DETECTED AT DIFFERENT POLARISATIONS IN MAESTRO DATA **c48**
Ronald G. Caves, Peter J. Harley, and Shaun Quegan *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 89-91 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Edge detection would appear to be a crucial tool for analyzing multi-polarized, multi-frequency, and multi-temporal Synthetic Aperture Radar (SAR) images. Edge structure provides a simple means for comparing different polarizations and frequencies, and for detecting changes over time. Due to the fact that edges and segments (homogeneous regions) are dual concepts, edge detection has an important role to play in identifying segments within which mean backscatter measurements for use in image classification can be made. As part of a general investigation into edge detection in SAR imagery, an initial investigation was carried out into the detectability and nature of edges in multi-polarized and multi-frequency SAR images. The contrast ratio (CR) operator was used to detect edges. This operator was previously shown to perform well at detecting edges in single-polarized and single-frequency SAR images.

LITHOLOGICAL AND TEXTURAL CONTROLS ON RADAR AND DIURNAL THERMAL SIGNATURES OF WEATHERED VOLCANIC DEPOSITS, LUNAR CRATER REGION, NEVADA **c48**

Jeffrey J. Plaut and Benoit Rivard (York Univ., Ontario.) *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 3: AIRSAR Workshop 1 Jun. 1992 p 92-95 (For primary document see N94-16731 03-42)
Avail: CASI HC A01/MF A02

Radar backscatter intensity as measured by calibrated synthetic aperture radar (SAR) systems is primarily controlled by three factors: local incidence angle, wavelength-scale roughness, and dielectric permittivity of surface materials. Radar observations may be of limited use for geological investigations of surface composition, unless the relationships between lithology and the above characteristics can be adequately understood. In arid terrains, such as the Southwest U.S., weathering signatures (e.g. soil development, fracturing, debris grain size and shape, and hill slope characteristics) are controlled to some extent by lithologic characteristics of the parent bedrock. These textural features of outcrops and their associated debris will affect radar backscatter to varying degrees, and the multiple-wavelength capability of the JPL Airborne SAR (AIRSAR) system allows sampling of textures at three distinct scales. Diurnal temperature excursions of geologic surfaces are controlled primarily by the thermal inertia of surface materials, which is a measure of the resistance of a material to a change in temperature. Other influences include albedo, surface slopes affecting insolation, local meteorological conditions and surface emissivity at the relevant thermal wavelengths. To first order, thermal inertia variations on arid terrain surfaces result from grain size distribution and porosity differences, at scales ranging from micrometers to tens of meters. Diurnal thermal emission observations, such as those made by the JPL Thermal Infrared Multispectral Scanner (TIMS) airborne instrument, are thus influenced by geometric surface characteristics at scales comparable to those controlling radar backscatter. A preliminary report on a project involving a combination of field, laboratory and remote sensing observations of weathered felsic-to basaltic volcanic rock units exposed in the southern part of the Lunar Crater Volcanic Field, in the Pancake Range of central Nevada is presented. Focus is on the relationship of radar backscatter cross sections at multiple wavelengths, apparent diurnal temperature excursions identified in multi-temporal TIMS images, surface geometries related to weathering style, and parent bedrock lithology. Different quantities effecting the accuracy of geodetic positioning by means of an inertial strapdown system are analyzed. The inertial sensors are the starting point of the theoretical analysis. Detailed models of a pendulous accelerometer, a rate integrating gyro and a ring laser gyro were introduced and discussed as examples of the method of the mathematical modeling. The transformations between the reference frames, which have be realized for the implementation of the model equation of inertial positioning, were discussed with regard to today's state of the art sensor technology. To obtain an overview of the behavior of the solutions of the differential equations simplified as a result of the above mentioned discussion, the stability of the linearized equations was analyzed, using analytical and numerical methods. Nevertheless, in the case at hand of a time variable system, only restricted statements based on the linearized equations are possible. Hence in the extensive simulations carried out the nonlinear model equations were used. The effect of different sensor parameters on position and orientation was simulated for trajectories of different dynamics. For adapting the course and the dynamics of the trajectories, observed data were used. The results obtained using a simple compensation algorithm are presented. A detailed representation of the nonlinear and linear system equations for different parametrizations of both the translation and the rotation was proposed. ESA

AN EXPERT SYSTEM SHELL FOR INFERRING VEGETATION CHARACTERISTICS: ATMOSPHERIC TECHNIQUES (TASK G) Final Report, Apr. - Oct. 1993
P. Ann Harrison and Patrick R. Harrison Oct. 1993 39 p
(Contract NAS5-30127; RTOP 462-61-14)
(NASA-CR-194570; NAS 1.26:194570; C931031-U-2R06) Avail: CASI HC A03/MF A01

The NASA VEGetation Workbench (VEG) is a knowledge based system that infers vegetation characteristics from reflectance data. The VEG Subgoals have been reorganized into categories. A new subgoal category 'Atmospheric Techniques' containing two new subgoals has been implemented. The subgoal Atmospheric Passes allows the scientist to take reflectance data measured at ground level and predict what the reflectance values would be if the data were measured at a different atmospheric height. The subgoal Atmospheric Corrections allows atmospheric corrections to be made to data collected from an aircraft or by a satellite to determine what the equivalent reflectance values would be if the data were measured at ground level. The report describes the implementation and testing of the basic framework and interface for the Atmospheric Techniques Subgoals. Author

DEVELOP ADVANCED NONLINEAR SIGNAL ANALYSIS TOPOGRAPHICAL MAPPING SYSTEM Monthly Technical Progress Report, Oct. 1993
Jen-Yi Jong 31 Oct. 1993 11 p
(Contract NAS8-39393)
(NASA-CR-194577; NAS 1.26:194577; TR-4002-93-10) Avail: CASI HC A03/MF A01

The SSME has been undergoing extensive flight certification and developmental testing, which involves some 250 health monitoring measurements. Under the severe temperature pressure, and dynamic environments sustained during operation, numerous major component failures have occurred, resulting in extensive engine hardware damage and scheduling losses. To enhance SSME safety and reliability, detailed analysis and evaluation of the measurements signal are mandatory to assess its dynamic characteristics and operational condition. Efficient and reliable signal detection techniques will reduce catastrophic system failure risks and expedite the evaluation of both flight and ground test data, and thereby reduce launch turn-around time. The basic objective of this contract are threefold: (1) Develop and validate a hierarchy of innovative signal analysis techniques for nonlinear and nonstationary time-frequency analysis. Performance evaluation will be carried out through detailed analysis of extensive SSME static firing and flight data. These techniques will be incorporated into a fully automated system. (2) Develop an advanced nonlinear signal analysis topographical mapping system (ATMS) to generate a Compressed SSME TOPO Data Base (CSTDB). This ATMS system will convert tremendous amounts of complex vibration signals from the entire SSME test history into a bank of succinct image-like patterns while retaining all respective phase information. A high compression ratio can be achieved to allow the minimal storage requirement, while providing fast signature retrieval, pattern comparison, and identification capabilities. (3) Integrate the nonlinear correlation techniques into the CSTDB data base with compatible TOPO input data format. Such integrated ATMS system will provide the large test archives necessary for a quick signature comparison. This study will provide timely assessment of SSME component operational status, identify probable causes of malfunction, and indicate feasible engineering solutions. The final result of this program will yield an ATMS system of nonlinear and nonstationary spectral analysis software package integrated with the Compressed SSME TOPO Data Base (CSTDB) on the same platform. This system will allow NASA engineers to retrieve any unique defect signatures and trends associated with different failure modes and anomalous phenomena over the entire SSME test history across turbo pump families. RESEARCH INTO THE INFLUENCE OF SPATIAL VARIABILITY AND SCALE ON THE PARAMETERIZATION OF HYDROLOGICAL PROCESSES Final Technical Report
Eric F. Wood 1993 240 p
(Grant NAGw-1392)
(NASA-CR-194610; NAS 1.26:194610) Avail: CASI HC A11/MF A03

The objectives of the research were as follows: (1) Extend the Representative Elementary Area (RE) concept, first proposed and developed in Wood et al, (1988), to the water balance fluxes of the interstorm period (redistribution, evapotranspiration and baseflow) necessary for the analysis of long-term water balance processes. (2) Derive spatially averaged water balance model equations for spatially variable soil, topography and vegetation, over A RANGE OF CLIMATES. This is a necessary step in our goal to derive consistent hydrologic results up to GCM grid scales necessary for global climate modeling. (3) Apply the above macroscale water balance equations with remotely sensed data and begin to explore the feasibility of parameterizing the water balance constitutive equations at GCM grid scale. For individual titles, see N94-16027 through N94-16034.

ON HYDROLOGIC SIMILARITY: A DIMENSIONLESS FLOOD FREQUENCY MODEL USING A GENERALIZED GEOMORPHOLOGIC UNIT HYDROGRAPH AND PARTIAL AREA RUNOFF GENERATION

Murugesu Sivapalan, Eric F. Wood, and Keith J. Beven (Lancaster Univ., England.) *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 16 p Repr. from Water Resources Research, v. 26, no. 1, Jan. 1990 p 43-58 (For primary document see N94-16026 03-43)

(Grants NAG5-491; USGS-14-08-0001-G1138)

(Paper-89WR01579) Avail: CASI HC A03/MF A03

One of the shortcomings of the original theory of the geomorphologic unit hydrograph (GUH) is that it assumes that runoff is generated uniformly from the entire catchment area. It is now recognized that in many catchments much of the runoff during storm events is produced on partial areas which usually form on narrow bands along the stream network. A storm response model that includes runoff generation on partial areas by both Hortonian and Dunne mechanisms was recently developed by the authors. In this paper a methodology for integrating this partial area runoff generation model with the GUH-based runoff routing model is presented; this leads to a generalized GUH. The generalized GUH and the storm response model are then used to estimate physically based flood frequency distributions. In most previous work the initial moisture state of the catchment had been assumed to be constant for all the storms. In this paper we relax this assumption and allow the initial moisture conditions to vary between storms. The resulting flood frequency distributions are cast in a scaled dimensionless framework where issues such as catchment scale and similarity can be conveniently addressed. A number of experiments are performed to study the sensitivity of the flood frequency response to some of the 'similarity' parameters identified in this formulation. The results indicate that one of the most important components of the derived flood frequency model relates to the specification of processes within the runoff generation model; specifically the inclusion of both saturation excess and Horton infiltration excess runoff production mechanisms. The dominance of these mechanisms over different return periods of the flood frequency distribution can significantly affect the distributional shape and confidence limits about the distribution. Comparisons with observed flood distributions seem to indicate that such mixed runoff production mechanisms influence flood distribution shape. The sensitivity analysis also indicated that the incorporation of basin and rainfall storm scale also greatly influences the distributional shape of the flood frequency curve. Author

SIMILARITY AND SCALE IN CATCHMENT STORM RESPONSE

Eric F. Wood, Murugesu Sivapalan (University of Western Australia, Nedlands.), and Keith Beven (Lancaster Univ., England.) *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 18 p Repr. from Reviews of Geophysics, v. 28, no. 1, Feb. 1990 p 1-18 (For primary document see N94-16026 03-43)

(Grants NAG5-491; USGS-14-08-0001-G1138; NERC-GR3/6264)

(Paper-89RG01615) Avail: CASI HC A03/MF A03

Until recently, very little progress had been made in understanding the relationship between small-scale variability of topography, soil, and rainfalls and the storm response seen at the catchment scale. The work reviewed here represents the first attempt at a systematic theoretical framework for such understanding in the context of surface runoff generation by different processes. The parameterization of hydrological processes over a range of scales is examined, and the concept of the 'representative elementary area' (REA) is introduced. The REA is a fundamental scale for catchment modeling at which continuum assumptions can be applied for the spatially variable controls and parameters, and spatial patterns no longer have to be considered explicitly. The investigation of scale leads into the concept of hydrologic similarity in which the effects of the environmental controls on runoff generation and flood frequency response be investigated independently of catchment scale. The paper reviews the authors' initial results and hopefully will motivate others to also investigate the issues of hydrologic scale and similarity. Author

EVAPOTRANSPIRATION AND RUNOFF FROM LARGE LAND AREAS: LAND SURFACE HYDROLOGY FOR ATMOSPHERIC GENERAL CIRCULATION MODELS

J. S. Famiglietti and Eric F. Wood *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 28 p Repr. from Surveys in Geophysics, v. 12, 1991 p 179-204 (For primary document see N94-16026 03-43)

(Grants NGT-60153; USGS-14-08-0001-G1753)

Avail: CASI HC A03/MF A03

A land surface hydrology parameterization for use in atmospheric GCM's is presented. The parameterization incorporates subgrid scale variability in topography, soils, soil moisture and precipitation. The framework of the model is the statistical distribution of a topography-soils index, which controls the local water balance fluxes, and is therefore taken to represent the large land area. Spatially variable water balance fluxes are integrated with respect to the topography-soils index to yield our large topography-soils distribution, and interval responses are weighted by the probability of occurrence of the interval. Grid square averaged land surface fluxes result. The model functions independently as a macroscale water balance model. Runoff ratio and evapotranspiration efficiency parameterizations are derived and are shown to depend on the spatial variability of the above mentioned properties and processes, as well as the dynamics of land surface-atmosphere interactions. HETEROGENEITY AND SCALING LAND-ATMOSPHERIC WATER AND ENERGY FLUXES IN CLIMATE SYSTEMS c47

Eric F. Wood *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 50 p Presented at the IHP/IAHS George Kovacs Colloquium on Space and Time Variability and Interdependencies in Various Hydrological Processes, Paris, France, 3-4 Jul. 1992 (For primary document see N94-16026 03-43)

(Grants NAG5-899)

Avail: CASI HC A03/MF A03

The effects of small-scale heterogeneity in land surface characteristics on the large-scale fluxes of water and energy in land-atmosphere system has become a central focus of many of the climatology research experiments. The acquisition of high resolution land surface data through remote sensing and intensive land-climatology field experiments (like HAPEX and FIFE) has provided data to investigate the interactions between microscale land-atmosphere interactions and macroscale models. One essential research question is how to account for the small scale heterogeneities and whether 'effective' parameters can be used in the macroscale models. To address this question of scaling, three modeling experiments were performed and are reviewed in the paper. The first is concerned with the aggregation of parameters and inputs for a terrestrial water and energy balance model. The second experiment analyzed the scaling behavior of hydrologic responses during rain events and between rain events. The third experiment compared the hydrologic responses from distributed models with a lumped model that uses spatially constant inputs and parameters. The results show that the patterns of small scale variations can be represented statistically if the scale is larger than a representative elementary area scale, which appears to be about 2 - 3 times the correlation length of the process. For natural catchments this appears to be about 1 - 2 sq km. The results concerning distributed versus lumped representations are more complicated. For conditions when the processes are nonlinear, then lumping results in biases; otherwise a one-dimensional model based on 'equivalent' parameters provides quite good results. Further research is needed to fully understand these conditions. Author (revised)

The validity of some of the simplifying assumptions in a conceptual water balance model is investigated by comparing simulation results from the conceptual model with simulation results from a three-dimensional physically based numerical model and with field observations. We examine, in particular, assumptions and simplifications related to water table dynamics, vertical soil moisture and pressure head distributions, and subsurface flow contributions to stream discharge. The conceptual model relies on a topographic index to predict saturation excess runoff and on Philip's infiltration equation to predict infiltration excess runoff. The numerical model solves the three-dimensional Richards equation describing flow in variably saturated porous media, and handles seepage face boundaries, infiltration excess and saturation excess runoff production, and soil driven and atmosphere driven surface fluxes. The study catchments (a 7.2 sq km catchment and a 0.64 sq km subcatchment) are located in the North Appalachian ridge and valley region of eastern Pennsylvania. Hydrologic data collected during the MACHYDRO 90 field experiment are used to calibrate the models and to evaluate simulation results. It is found that water table dynamics as predicted by the conceptual model are close to the observations in a shallow water well and therefore, that a linear relationship between a topographic index and the local water table depth is found to be a reasonable assumption for catchment scale modeling. However, the hydraulic equilibrium assumption is not valid for the upper 100 cm layer of the unsaturated zone and a conceptual model that incorporates a root zone is suggested. Furthermore, theoretical subsurface flow characteristics from the conceptual model are found to be different from field observations, numerical simulation results, and theoretical baseflow recession characteristics based on Boussinesq's groundwater equation.

A DETAILED MODEL FOR SIMULATION OF CATCHMENT SCALE SUBSURFACE HYDROLOGIC PROCESSES
Claudio Paniconi and Eric F. Wood *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 20 p Repr. from Water Resources Research, v. 29, no. 6, Jun. 1993 p 1601-1620 Sponsored in part by the Pittsburgh Supercomputing Center (For primary document see N94-16026 03-43)
(Grants NAG5-899; NAG5-1249)
(Paper-92WR02333) Avail: CASI HC A03/MF A03

A catchment scale numerical model is developed based on the three-dimensional transient Richards equation describing fluid flow in variably saturated porous media. The model is designed to take advantage of digital elevation data bases and of information extracted from these data bases by topographic analysis. The practical application of the model is demonstrated in simulations of a small subcatchment of the Konza Prairie reserve near Manhattan, Kansas. In a preliminary investigation of computational issues related to model resolution, we obtain satisfactory numerical results using large aspect ratios, suggesting that horizontal grid dimensions may not be unreasonably constrained by the typically much smaller vertical length scale of a catchment and by vertical discretization requirements. Additional tests are needed to examine the effects of numerical constraints and parameter heterogeneity in determining acceptable grid aspect ratios. In other simulations we attempt to match the observed streamflow response of the catchment, and we point out the small contribution of the streamflow component to the overall water balance of the catchment.

EFFECTS OF SPATIAL VARIABILITY AND SCALE ON AREAL -AVERAGE EVAPOTRANSPIRATION
J. S. Famiglietti and Eric F. Wood *In its* Research into the Influence of Spatial Variability and Scale on the Parameterization of Hydrological Processes 1993 38 p Submitted for publication (For primary document see N94-16026 03-43)
(Grants NGT-60153)
Avail: CASI HC A03/MF A03

This paper explores the effect of spatial variability and scale on areally-averaged evapotranspiration. A spatially-distributed water and energy balance model is employed to determine the effect of explicit patterns of model parameters and atmospheric forcing on modeled areally-averaged evapotranspiration over a range of increasing spatial scales. The analysis is performed from the local scale to the catchment scale. The study area is King's Creek catchment, an 11.7 sq km watershed located on the native tallgrass prairie of Kansas. The dominant controls on the scaling behavior of catchment-average evapotranspiration are investigated by simulation, as is the existence of a threshold scale for evapotranspiration modeling, with implications for explicit versus statistical representation of important process controls. It appears that some of our findings are fairly general, and will therefore provide a framework for understanding the scaling behavior of areally-averaged evapotranspiration at the catchment and larger scales.

This grant is funded as a part of a program in which both research and educational impact are intended. Research work under this grant is directed at the understanding and use of future hyperspectral data such as that from imaging spectrometers. Specifically, the objectives of the work are (1) to prepare suitable means for analyzing data from sensors which have large numbers of spectral bands, (2) to advance the fundamental understanding of the manner in which soils and vegetative materials reflect high spectral resolution optical wavelength radiation, and (3) to maximize the impact of the results on the educational community. Over the life of the grant, the work has thus involved basic Earth science research and information system technique understanding and development in a mutually supportive way, however, more recently it has become necessary to focus the work primarily on areas (1) and (3). During the last year, the level of effort on this grant has been reduced to half its previous value. We have also been advised that this grant will end with the current year, thus this will be the penultimate semiannual progress summary. Derived from text

This report is to develop and build a deep-sea mapping sonar system, which was to be operated on delivery by the Naval Oceanographic Office (Code OW). Intended as the first increment of a multi-part grant, it was decided in 1991 by the ONR Contracts and Grants Office that the second and subsequent funding increments were to be carried out on a contract rather than grant basis, and thus, the present grant was allowed to expire in 1991 and a contract was initiated to complete the project. The description here is of the successful completion of development efforts under the grant component of the effort; the contract effort continues as of this date (6/93), with the principal deliverables completed, tested and delivered to NAVOCEANO for operation, but some portions of the work (and the contract period) and some expansion work remain unfinished. Propagation of energy (either acoustic or electromagnetic energy) through the region of the atmosphere close to the earth's surface depends on estimates of the vertical structure of wind, pressure, temperature, humidity, and refractive index near the earth's surface. To help predict these vertical structures, the TGRAD model has been developed. The model is based on flux-profile methods, requiring simple meteorological inputs as functions of time. The model's original purpose was to predict the vertical temperature gradient profile, hence the name TGRAD. The TGRAD model has been compared against a predecessor model (the Deardorff model) and has proven to characterize the near-surface atmosphere much better under foliated conditions. It characterizes the daytime atmosphere well under all conditions studied. It characterizes the nocturnal atmosphere well until the critical Richardson number is reached. For stronger nocturnal inversions an approach is discussed that may be capable of treating these conditions. The principal improvement provided by this model is the development of sensible and latent heat flux equations that more accurately account for a surface layer partially covered by foliage. DTIC

The process leading to the formulation of international research programs, aimed at using Earth Observation Systems (EOS) to understand the processes which govern global climate, is described. This research is related to the international scientific community, national funding agencies, intergovernmental cooperation, and private industry. The plan to develop a full EOS space measurement system based on NASA, ESA and Japanese platform(s) is discussed. The role of this EOS in the U.S. global climate research program is considered. The appropriate balance between ground based and space based research activities is stressed. A Netherlands perspective concerning research on land surface processes and future EOS is given. Future developments of general circulation models and of land surface models are discussed. ESA

A conceptual design for the Two-Dimensional, Electronically Steered Thinned Array Radiometer (ESTAR) is described. This instrument is a synthetic aperture microwave radiometer that operates in the L-band frequency range for the measurement of soil moisture and ocean salinity. Two auxiliary instruments, an 8-12 micron, scanning infrared radiometer and a 0.4-1.0 micron, charge coupled device (CCD) video camera, are included to provided data for sea surface temperature measurements and spatial registration of targets respectively. The science requirements were defined by Goddard Space Flight Center. Instrument and the spacecraft configurations are described for missions using the Pegasus and Taurus launch vehicles. The analyses and design trades described include: estimations of size, mass and power, instrument viewing coverage, mechanical design trades, structural and thermal analyses, data and communications performance assessments, and cost estimation.

TIMS PERFORMANCE EVALUATION SUMMARY
Bruce Spiering, G. Meeks, J. Anderson, S. Jaggi, and S. Kuo *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 1-3 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16597*# Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.
A QUANTITATIVE ANALYSIS OF TIMS DATA OBTAINED ON THE LEARJET 23 AT VARIOUS ALTITUDES
S. Jaggi *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 4-6 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16598*# Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.
ANALYSIS OF TIMS PERFORMANCE SUBJECTED TO SIMULATED WIND BLAST
S. Jaggi and S. Kuo *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 7-9 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16599*# Jet Propulsion Lab., California Inst. of Tech., Pasadena.
SENSITIVITY OF BLACKBODY REFERENCE PANELS TO WIND BLAST
Gordon Hoover *In its* Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 10-12 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16600*# JAPEX Geoscience Inst., Tokyo (Japan).
COMPARISON OF PRELIMINARY RESULTS FROM AIRBORNE ASTER SIMULATOR (AAS) WITH TIMS DATA
Yoshiaki Kannari, Franklin Mills, Hiroshi Watanabe, Teruya Ezaka, Tatsuhiko Narita, and Sheng-Huei Chang (Geophysical and Environmental Research, Inc., New York, NY.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 13-15 Sponsored in part by Japan Resources Observation System Organization (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16601*# Tokyo Univ. (Japan). Dept. of Mineral Development Engineering.
APPLICATION OF SPLIT WINDOW TECHNIQUE TO TIMS DATA
Tsuneo Matsunaga, Shuichi Rokugawa, and Yoshinori Ishii *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 16-18 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16603*# National Aeronautics and Space Administration. John C. Stennis Space Center, Bay Saint Louis, MS.
AN ALGORITHM FOR THE ESTIMATION OF BOUNDS ON THE EMISSIVITY AND TEMPERATURES FROM THERMAL MULTISPECTRAL AIRBORNE REMOTELY SENSED DATA
S. Jaggi (Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.), D. Quattrochi, and R. Baskin (Geological Survey, Salt Lake City, UT.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 22-24 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16604*# National Aeronautics and Space Administration. John C. Stennis Space Center, Bay Saint Louis, MS.
MULTI-RESOLUTION PROCESSING FOR FRACTAL ANALYSIS OF AIRBORNE REMOTELY SENSED DATA
S. Jaggi (Lockheed Engineering and Sciences Co., Bay Saint Louis, MS.), D. Quattrochi, and N. Lam (Louisiana State Univ., Baton Rouge.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 25-27 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16605*# Geological Survey, Reston, VA.
PRELIMINARY ANALYSIS OF THERMAL-INFRARED MULTISPECTRAL SCANNER DATA OF THE IRON HILL, COLORADO CARBONATITE-ALKALIC ROCK COMPLEX
Lawrence C. Rowan, Kenneth Watson (Geological Survey, Denver, CO.), and Susanne H. Miller (Geological Survey, Denver, CO.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 28-30 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16606*# Hawaii Univ., Honolulu. Inst. of Planetary Geosciences.
THE USE OF TIMS FOR MAPPING DIFFERENT PAHOEHOE SURFACES: MAUNA IKI, KILAUEA
Scott K. Rowland *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 31-33 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16607*# Arizona State Univ., Tempe. Dept. of Geology.
EJECTA PATTERNS OF METEOR CRATER, ARIZONA DERIVED FROM THE LINEAR UN-MIXING OF TIMS DATA AND LABORATORY THERMAL EMISSION SPECTRA
Michael S. Ramsey and Philip R. Christensen *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 2: TIMS Workshop 1 Jun. 1992 p 34-36 (For primary document see N94-16595 03-42)
Avail: CASI HC A01/MF A01

N94-16668*# California Univ., Davis. Dept. of Land, Air and Water Resources.
USING AVIRIS IMAGES TO MEASURE TEMPORAL TRENDS IN ABUNDANCE OF PHOTOSYNTHETIC AND NONPHOTOSYNTHETIC CANOPY COMPONENTS
Susan L. Ustin, Milton O. Smith (Washington Univ., Seattle.), Dar Roberts (Washington Univ., Seattle.), John A. Gamon (California State Univ., Los Angeles.), and Christopher B. Field (Carnegie Institution of Washington, Stanford, CA.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 5-7 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16669*# Colorado Univ., Boulder. Center for the Study of Earth from Space.
UNMIXING AVIRIS DATA TO PROVIDE A METHOD FOR VEGETATION FRACTION SUBTRACTION
J. A. Zamudio *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 8-10 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16670*# Geological Survey, Denver, CO.
MAPPING THE MINERALOGY AND LITHOLOGY OF CANYONLANDS, UTAH WITH IMAGING SPECTROMETER DATA AND THE MULTIPLE SPECTRAL FEATURE MAPPING ALGORITHM
Roger N. Clark, Gregg A. Swayze, and Andrea Gallagher *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 11-13 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16672*# California State Univ., Los Angeles.
EVALUATION OF SPATIAL PRODUCTIVITY PATTERNS IN AN ANNUAL GRASSLAND DURING AN AVIRIS OVERFLIGHT
John A. Gamon, Christopher B. Field (Carnegie Institution of Washington, Stanford, CA.), and Susan L. Ustin (California Univ., Davis.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 17-19 Sponsored in part by A. W. Mellon Foundation (For primary document see N94-16666 03-42)
(CIW-Publ-1134) Avail: CASI HC A01/MF A02

N94-16673*# Naval Research Lab., Bay Saint Louis, MS.
HYPERSPECTRAL MODELING FOR EXTRACTING AEROSOLS FROM AIRCRAFT/SATELLITE DATA
G. Daniel Hickman and Michael J. Duggin (State Univ. of New York, Syracuse.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 20-22 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16674*# Colorado Univ., Boulder. Center for the Study of Earth from Space.
THE SPECTRAL IMAGE PROCESSING SYSTEM (SIPS): SOFTWARE FOR INTEGRATED ANALYSIS OF AVIRIS DATA
F. A. Kruse, A. B. Lefkoff, J. W. Boardman, K. B. Heidebrecht, A. T. Shapiro, P. J. Barloon, and A. F. H. Goetz *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 23-25 (For primary document see N94-16666 03-42)
(Contract NAS5-30552; NAGw-1601)
Avail: CASI HC A01/MF A02

N94-16675*# Brown Univ., Providence, RI. Dept. of Geological Sciences.
FIRST RESULTS FROM ANALYSIS OF COORDINATED AVIRIS, TIMS, AND ISM (FRENCH) DATA FOR THE RONDA (SPAIN) AND BENI BOUSERA (MOROCCO) PERIDOTITES
J. F. Mustard, S. Hurtrez (Paris-Sud Univ., Orsay, France.), P. Pinet (Centre National d'Etudes Spatiales, Toulouse, France.), and C. Sotin (Paris-Sud Univ., Orsay, France.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 26-28 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16676*# Geological Survey, Reston, VA.
AVIRIS STUDY OF DEATH VALLEY EVAPORITE DEPOSITS USING LEAST-SQUARES BAND-FITTING METHODS
J. K. Crowley and R. N. Clark (Geological Survey, Denver, CO.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 29-31 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16677*# Washington Univ., Seattle. Dept. of Geological Sciences.
A FIELD MEASURE OF THE SHADE FRACTION
Alan R. Gillespie, Milton O. Smith, and Donald E. Sabol *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 32-34 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16678*# Colorado Univ., Boulder. Center for the Study of Earth from Space.
A LINEAR SPECTRAL MATCHING TECHNIQUE FOR RETRIEVING EQUIVALENT WATER THICKNESS AND BIOCHEMICAL CONSTITUENTS OF GREEN VEGETATION
Bo-Cai Gao and Alexander F. H. Goetz *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 35-37 (For primary document see N94-16666 03-42)
(Contract NAS5-30552)
Avail: CASI HC A01/MF A02

N94-16679*# Washington Univ., Seattle. Dept. of Geological Sciences.
MAPPING THE SPECTRAL VARIABILITY IN PHOTOSYNTHETIC AND NON-PHOTOSYNTHETIC VEGETATION, SOILS, AND SHADE USING AVIRIS
Dar A. Roberts, Milton O. Smith, Donald E. Sabol, John B. Adams, and Susan L. Ustin (California Univ., Davis.) *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 38-40 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16681*# Centre d'Etude Spatiale des Rayonnements, Toulouse (France).
RETRIEVAL OF BIOPHYSICAL PARAMETERS WITH AVIRIS AND ISM: THE LANDES FOREST, SOUTH WEST FRANCE
F. Zagolski, J. P. Gastellu-Etchegorry, E. Mougin, G. Giordano, G. Marty, T. LeToan, and A. Beaudoin *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 44-46 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16682*# Geological Survey, Denver, CO.
GROUND-TRUTHING AVIRIS MINERAL MAPPING AT CUPRITE, NEVADA
Gregg Swayze, Roger N. Clark, Fred Kruse (Colorado Univ., Boulder.), Steve Sutley, and Andrea Gallagher *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 47-49 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16683*# University Coll. of Swansea (Wales). Dept. of Geography.
EXPLORING THE REMOTE SENSING OF FOLIAR BIOCHEMICAL CONCENTRATIONS WITH AVIRIS DATA
Geoffrey M. Smith and Paul J. Curran *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 50-52 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16684*# California Univ., Santa Barbara. Dept. of Biological Sciences.
SEASONAL AND SPATIAL VARIATIONS IN PHYTOPLANKTONIC CHLOROPHYLL IN EUTROPHIC MONO LAKE, CALIFORNIA, MEASURED WITH THE AIRBORNE VISIBLE AND INFRARED IMAGING SPECTROMETER (AVIRIS)
John M. Melack and Mary Gastil *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 53-55 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16686*# Geological Survey, Denver, CO.
MAPPING VEGETATION TYPES WITH THE MULTIPLE SPECTRAL FEATURE MAPPING ALGORITHM IN BOTH EMISSION AND ABSORPTION
Roger N. Clark, Gregg A. Swayze, Christopher Koch, and Cathy Ager *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 60-62 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16688*# Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen (Germany). Inst. for Microwave Technologies.
MAC EUROPE 1991: EVALUATION OF AVIRIS, GER IMAGING SPECTROMETRY DATA FOR THE LAND APPLICATION TESTSITE OBERPFAFFENHOFEN
F. Lehmann, R. Richter, H. Rothfuss, K. Werner, P. Hausknecht, A. Mueller, and P. Strobl *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 66-68 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

N94-16689*# Washington Univ., Seattle. Dept. of Geological Sciences.
USING ENDMEMBERS IN AVIRIS IMAGES TO ESTIMATE CHANGES IN VEGETATIVE BIOMASS
Milton O. Smith, John B. Adams, Susan L. Ustin (California Univ., Davis.), and Dar A. Roberts *In* JPL, Summaries of the Third Annual JPL Airborne Geoscience Workshop. Volume 1: AVIRIS Workshop 1 Jun. 1992 p 69-71 (For primary document see N94-16666 03-42)
Avail: CASI HC A01/MF A02

PROGRESS IN THE CONCENTRATOR INITIATIVE PROGRAM
A. B. Maish 1992 7 p Presented at the 23rd IEEE Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-015006; SAND-92-2831C; CONF-930540-8) Avail: CASI HC A02/MF A01

Progress made by the eight participating cell and collector manufacturers since the beginning of the U.S. Department of Energy's multiyear photovoltaic Concentrator Initiative program is reviewed. Point and line-focus cell manufacturers achieved peak efficiencies between 19% and 25% with designs that could be manufactured commercially. Collector manufacturers delivered prototype hardware of point and line-focus collectors representing commercially producible technology. DOE

REVISITING THE BCS, A MEASUREMENT SYSTEM FOR CHARACTERIZING THE OPTICS OF SOLAR COLLECTORS
J. W. Strachan 1992 12 p Presented at the 39th International Instrumentation Symposium, Albuquerque, NM, 2-6 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-015030; SAND-92-2789C; CONF-930561-6) Avail: CASI HC A03/MF A01

The Beam Characterization System is being employed at the Sandia's National Solar Thermal Test Facility to characterize the optical performance of heliostats, point-focus solar collectors, and their optical sub-elements as part of the on-going task to develop solar thermal technologies. With this measurement system, images of concentrated solar flux are acquired using digital imaging and processed to obtain such measures of the collector's optical performance as beam power, flux distribution, and beam diameter. Key system elements are a diffusely reflective target for imaging collector beams, meteorological instrumentation including a flux gauge to measure flux at one point in the beam, and a calibration technique to establish a pixel-intensity to flux-density conversion factor for the image. The system is employed in a variety of collector tests such as beam quality, tracking error, and wind effects. The paper describes the Beam Characterization System and its components and presents, for illustration, sample test results. An analysis of the Beam Characterization System's sources of measurement error is presented. Lastly, measurement techniques that employ the BCS to align heliostats and to measure or estimate collector surface slope errors are described. DOE

RECENT ADVANCES IN OUTDOOR PERFORMANCE EVALUATION OF PV SYSTEMS
M. A. Quintana, D. L. King, J. E. Cannon, J. R. Woodworth, W. E. Boyson,

N. P. Adams, and D. E. Ellibee 1992 6 p Presented at the 23rd IEEE Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993
(Contract DE-AC04-76DP-00789)
(DE93-015031; SAND-92-2829C; CONF-930540-2) Avail: CASI HC A02/MF A01

Sandia's Photovoltaic Technology Laboratory (PTEL) routinely performs outdoor tests of a variety of one-sun and concentrator PV modules. The authors' experience is that while outdoor testing has its own set of problems, it can produce results that are more directly applicable to 'field' conditions than testing in solar simulators. They have recently improved both the hardware and software at the PTEL to improve their accuracy and to deal with the special set of problems encountered in outdoor testing. Improvements in hardware include a computer-controlled solar tracker that allows us to test arrays up to 21 sq m in size, infrared imaging of modules, and electronic loads that allow us to test components with outputs up to 1,800 watts. Improvements in software include real-time monitoring of data collection; a relational data base that has improved the reliability of test setups, operations, and analyses; and a standardized reporting process that relates module performance to a number of environmental parameters. DOE

PROPOSED GUIDELINES FOR REPORTING PERFORMANCE OF A SOLAR DISH/STIRLING ELECTRIC GENERATION SYSTEM
W. B. Stine (California State Polytechnic Univ., Pomona.) and M. A. Powell 1992 8 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-016493; SAND-92-2870C; CONF-930804-9) Avail: CASI HC A02/MF A01

Experimental performance data from dish/Stirling system testing can be analyzed to generate a system performance model. An approach to developing an experimentally based performance model of a dish/Stirling system is given. Two methods for analyzing the experimental data are described. To provide information that will permit comparison of dish/Stirling systems, it is necessary to define many of the details involved in calculating system performance data such as the net system output and system solar-to-electric efficiency. This paper describes a set of guidelines for these calculations, based on past experience, especially with the Vanguard dish/Stirling system. Also presented are a set of rating conditions at which a maximum value for system efficiency can be calculated. Comparison between systems of their rated peak solar-to-electric efficiency is made possible when these rating conditions are in common use by manufacturers and testing agencies. DOE

N94-16160# Pacific Northwest Lab., Richland, WA.
CHEMICAL INTERACTIONS BETWEEN INTERCONNECT AND ELECTRODE MATERIALS DURING SINTERING IN SOLID OXIDE FUEL CELLS
T. R. Armstrong, L. A. Chick, and J. L. Bates May 1993 10 p Presented at the 3rd International Symposium on Solid Oxide Fuel Cells, Honolulu, HI, 16-21 May 1993
(Contract DE-AC06-76RL-01830)
(DE93-015696; PNL-SA-21621; CONF-9305100-2) Avail: CASI HC A02/MF A01

Chemical interactions and interdiffusion between the interconnect, (LaCa)CrO3 and (YCa)CrO3 and the anode, Ni(center dot)ZrO2, and cathode, (LaSr)MnO3 and (YCa)MnO3, were evaluated from 1300 to 1500C. Reaction of (LaCa)CrO3 and Ni(center dot)ZrO2 cermet resulted in the formation of NiCr2O4 spinel, while reaction of (YCa)CrO3 and Ni(center dot)ZrO2 resulted in the formation of both NiCr2O4 and CaZrO3, at all temperatures. Interactions between the chromites and manganites resulted in the formation of a solid solution. Dense reaction layers were observed near the interface of Ni(center dot)ZrO2/(LaCa)CrO3 and Ni(center dot)ZrO2/(YCa)CrO3 samples. These dense regions were enriched in calcium and chromium, resulting from liquid migration from the chromite to the anode. Nearly ideal interfaces were observed between (LaSr)MnO3 and (LaCa)CrO3. Interactions between (YCa)CrO3 and (YCa)MnO3 resulted in the formation of a CaCrO4 rich layer along the interface. DOE

HYDRIDE-CONTAINING MOLTEN SALTS AND THEIR TECHNOLOGY IMPLICATIONS Interim Report
Bor Y. Liaw Mar. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1673)
(AD-A266458; TR-01-ONR) Avail: CASI HC A03

Hydride-conducting molten salts such as LiH in eutectic LiCl-KCl are attractive electrolyte systems for intermediate-temperature applications. The chemically reducing characteristics of these hydride melts provide a unique method to clean metal surfaces. The high conductivity of these hydride melts makes them the best electrolytes for hydrogen-based energy applications at intermediate temperatures. We will review some earlier work on hydride-conducting molten salts and their potential applications in energy technology. We will also describe some recent work on these hydride-containing molten salts for energy conversion and storage applications, including hydrogen sensing and hydrogen storage, electrochemical characterizations, and thermodynamic and kinetic investigations of metal-hydrogen reactions. More recently, lithium deuteride containing eutectic LiCl-KCl melts have been used for excess heat production by the process of electrolysis to charge deuterium into metal matrix such as Pd and Ti. From these studies we illustrate the prospects of this hydride molten salt technology and its implications for the use in intermediate-temperature electro-chemical energy conversion configurations. It will also reveal some interesting electrochemical aspects involved in the processes. DTIC

STATUS OF MOLTEN CARBONATE FUEL CELL TECHNOLOGY DEVELOPMENT
E. L. Parsons, Jr., M. C. Williams, and T. J. George 1993 12 p Presented at the 3rd International Symposium on Carbonate Fuel Cell Technology, Honolulu, HI, 16-21 May 1993
(DE93-015666; DOE/METC-C/93/7082; CONF-9305101-2) Avail: CASI HC A03/MF A01

The MCFC technology has been identified by the DOE as a promising product for commercialization. Development of the MCFC technology supports the National Energy Strategy. Review of the status of the MCFC technology indicates that the MCFC technology developers are making rapid and significant progress. Manufacturing facility development and extensive testing is occurring. Improvements in performance (power density), lower costs, improved packaging, and scale up to full height are planned. MCFC developers need to continue to be responsive to end-users in potential markets. It will be market demands for the correct product definition which will ultimately determine the character of MCFC power plants. There is a need for continued MCFC product improvement and multiple product development tests. DOE

BIOMASS ENERGY: STATE OF THE TECHNOLOGY PRESENT OBSTACLES AND FUTURE POTENTIAL
Larry Dobson 23 Jun. 1993 113 p
(Contract DE-FG01-89CE-15425)
(DE93-016295; DOE/CE-15425/T11) Avail: CASI HC A06/MF A02

The prevailing image of wood and waste burning as dirty and environmentally harmful is no longer valid. The use of biomass combustion for energy can solve many of our nation's problems. Wood and other biomass residues that are now causing expensive disposal problems can be burned as cleanly and efficiently as natural gas, and at a fraction of the cost. New breakthroughs in integrated waste-to-energy systems, from fuel handling, combustion technology and control systems to heat transfer and power generation, have dramatically improved system costs, efficiencies, cleanliness of emissions, maintenance-free operation, and end-use applications. Increasing costs for fossil fuels and for waste disposal strict environmental regulations and changing political priorities have changed the economics and rules of the energy game. This report describes the new rules, new playing field and key players, in the hopes that those who make our nation's energy policy and those who play in the energy field will take biomass seriously and promote its use. DOE

MONOLITHIC, TWO-TERMINAL InP/Ga(0.47)In(0.53)As TANDEM SOLAR CELLS

M. W. Wanlass, J. S. Ward, K. A. Emery, and T. J. Coutts 1993 5 p Presented at the 5th International Conference on InP and Related Materials, Paris, France, 18-22 Apr. 1993

(Contract DE-AC02-83CH-10093)

(DE93-014037; CONF-9304151-1) Avail: CASI HC A01/MF A01

Monolithic InP/Ga(0.7)In(0.53)As tandem solar cells have been studied extensively in our laboratory over the last 4 years. Using the three-terminal approach, the tandem cell performance progressed rapidly, and improvements in the epitaxial growth and device processing procedures eventually led to a terrestrial concentrator tandem cell efficiency of 31.8%. Recently, our research has been directed towards the development of two-terminal (i.e., series-connected) monolithic InP/Ga(0.47)In(0.53)As tandem cells. Two-terminal tandem cells are desirable because they can be substituted directly for single-junction solar cells in photovoltaic module circuits that are being manufactured presently. Furthermore, in principle, two-terminal tandems should take less time to grow and process than three-terminal tandems, which would lead to reduced cell manufacturing costs. The data obtained from our previous study of three-terminal InP/Ga(0.47)In(0.53)As tandem cells have shown that the potential performance of two-terminal InP/Ga(0.47)In(0.53)As is quite high. Two fundamental problems must be addressed to realize high-performance, two-terminal cells. First, an ohmic electrical interconnect between the top and bottom subcells must be integrated into the monolithic structure to connect the subcells in series. The optical and joule losses in the interconnect should be negligible compared to the tandem cell output. Second, because the subcells are connected in series, techniques for matching the subcell photocurrents and maximizing the tandem cell photocurrent, under relevant solar spectra, are necessary to achieve the highest tandem cell efficiency. In this paper, we describe preliminary progress towards solving these problems and outline directions for future work.

HIGH HEAT FLUX ENGINEERING IN SOLAR ENERGY APPLICATIONS

C. P. Cameron 1993 12 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993

(Contract DE-AC04-76DP-00789)

(DE93-016500; SAND-93-0229C; CONF-930722-4) Avail: CASI HC A03/MF A01

Solar thermal energy systems can produce heat fluxes in excess of 10,000 kW/sq m. This paper provides an introduction to the solar concentrators that produce high heat flux, the receivers that convert the flux into usable thermal energy, and the instrumentation systems used to measure flux in the solar environment. References are incorporated to direct the reader to detailed technical information. DOE

NUMERICAL MODELLING OF AN ACTIVE DIRECT NONPOTABLE HOT WATER HEATING SYSTEM MAKING USE OF THE ENERGY OF SOLAR RADIATION [NUMERYCZNE MODELOWANIE AKTYWNEGO BEZPOSREDNIEGO SYSTEMU PODGRZEWU CIEPLEJ WODY UZYTKOWEJ Z WYKORZYSTANIEM ENERGII PROMIENIOWANIA SLONECZNEGO]

Ryszard Wnuk 1991 37 p In POLISH

(IFTR-38/1991) Avail: CASI HC A03/MF A01

This paper presents the principles, descriptions and results from a program numerically simulating the operation of a direct hot water heating system utilizing solar energy. Discussions of the water heating systems and a simulated unit are given. The study primarily focuses on the solar energy accumulation reservoir for which a comprehensive reservoir model is given together with experimental testing results obtained on site. Also provided are the meteorological data utilized; data relating to the water delivery model and calculated parameters of the unit and its efficiency factor (the efficiency 'H'). Applied estimates derived from a numerical analysis of the simulated unit together with associated results are provided.

ASSESSMENT OF TRENDS IN THE DEVELOPMENT OF RESIDENTIAL BUILDINGS FROM THE STANDPOINT OF THE FUEL AND ENERGY REQUIREMENTS [OCENA KIERUNKOW ROZWOJU BUDOWNICTWA MIESZKANIOWEGO Z PUNKTU WIDZENIA ZAPOTRZEBOWANIA NA PALIWA I ENERGIE]

Stanislaw Chyrczakowski 1991 49 p In POLISH

(IFTR-6/1991) Avail: CASI HC A03/MF A01

An assessment of the developmental trends in domestic housing construction from the viewpoint of energy and fuel consumption requirements was presented. The introduction provides an analysis of the developmental trends in domestic housing construction based on data reported in the literature on this topic. Primary attention is focused on technological issues and trends in construction that have a direct effect on fuel and energy use. The problem of calculating energy use in construction of residential housing units is presented. It is demonstrated that there exists significant differences between different technologies for housing construction. Monolithic technology utilizes the greatest energy (buildings for housing a large number of families), while the least energy is used by brick structures employing prefabricated elements (single family homes). Aspects of energy use for domestic housing heating applications as a function of their architectural design, height, shape, etc. are discussed. It is demonstrated that the decisive factor in energy use is not principally the building construction techniques (in the sense of the classification based on the support structure) but rather is the so-called exterior sealing methods that may or may not be related to the construction technique for the building overall. The height and shape of the building also play an important role. Supplementary aspects relating to the development of construction that the author believes are timely developments in the development of domestic housing construction in Poland were presented on the basis of the model calculations.

A TEN YEAR REVIEW OF PERFORMANCE OF PHOTOVOLTAIC SYSTEMS

A. L. Rosenthal (Southwest Technology Development Inst., Las Cruces, NM.), S. J. Durand (Southwest Technology Development Inst., Las Cruces, NM.), and M. G. Thomas 1993 3 p Presented at the 23rd IEEE Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993

(Contract DE-AC04-76DP-00789)

(DE93-015649; SAND-93-1252C; CONF-930540-9) Avail: CASI HC A01/MF A01

This paper presents data compiled by the Photovoltaic Design Assistance Center at Sandia National Laboratories from more than eighty field tests performed on over thirty-five photovoltaic systems in the United States during the last ten years. The recorded performance histories, failure rates, and degradation of post-Block 4 modules and balance-of-system (BOS) components are described in detail.

ENERGY FROM THE SUN: EVOLUTION OF FEDERAL SUPPORT FOR SOLAR ENERGY M.S. Thesis

Paul C. Clark 29 May 1993 84 p

(AD-A267944; AFIT/CI/CIA-93-030) Avail: CASI HC A05/MF A01

Early civilizations workshipped the sun and relied upon it as a source of energy. Later, with the discovery of oil and coal, man looked to a new deity, fossil fuel, and the sun's importance as an energy source began to wane. Events in the last twenty years, however, indicate the sun is more important than ever as a future source of renewable energy. But, the development and commercial application of solar energy technologies will never occur without the commitment of the American people and their elected representatives in Congress.

The development of technologically advanced, high-efficiency wind turbines continues to be a high-priority activity of the US wind industry. The National Renewable Energy Laboratory (formerly the Solar Energy Research Institute), sponsored by the US Department of Energy (DOE), has initiated the Advanced Wind Turbine Program to assist the wind industry in the development of a new class of advanced wind turbines. The initial phase of the program focused on developing conceptual designs for near-term and advanced turbines. The goal of the second phase of this program is to use the experience gained over the last decade of turbine design and operation combined with the latest existing design tools to develop a turbine that will produce energy at $0.05 per kilowatt-hour (kWh) in a 5.8-m/s (13-mph) wind site. Three contracts have been awarded, and two more are under negotiation in the second phase. The third phase of the program will use new innovations and state-of-the-art wind turbine design technology to produce a turbine that will generate energy at $0.04/kWh in a 5.6-m/s wind site. Details of the third phase will be announced in early 1993. DOE

HyperVentilate: DECISION-SUPPORT SOFTWARE FOR SOIL VAPOR EXTRACTION TECHNOLOGY APPLICATION
C. A. Kruger and J. G. Morse Feb. 1993 172 p Sponsored by EPA, Cincinnati, OH Prepared in cooperation with Midwest Research Inst., Falls Church, VA
(Contract EPA-68-C2-0108)
(PB93-134880; EPA/600/R-93/028; AEPA/SW/DK-A93/033A) Avail: CASI HC A08/MF A02

Soil vapor extraction (SVE) is a proven, in situ corrective action technology that can remove volatile organic compounds (VOC) and selected residual petroleum hydrocarbons from unsaturated soils. To assist regulators, investigators, and UST owners in evaluating whether SVE is an appropriate cleanup technology for use at UST sites, decision-support software entitled HyperVentilate has been developed. HyperVentilate is an interactive, software guidance system for evaluating the feasibility of using SVE at a specific site based on site and contaminant characteristics. HyperVentilate is designed to do the following: (1) identify the level of site data required to evaluate SVE systems; (2) evaluate soil permeability test results; (3) approximate the minimum number of extraction wells likely to be needed; and (4) provide a rough approximation of the system's desired and maximum removal rates. The document provides guidance in evaluating the use of the IBM-compatible version of HyperVentilate that requires a computer equipped with (minimally) a 80386 processor, 4 MB RAM, DOS 3.1, Microsoft Windows 3.x, and Spinnaker PLUS 2.5. An overview of SVE principles and procedures is presented along with the basic model principles and a sensitivity analysis of HyperVentilate. A sample application of the software is also presented using data from an actual UST site. NTIS

PROJECTIONS OF FUTURE CO2
I. G. Enting (Commonwealth Scientific and Industrial Research Organization, Mordialoc, Australia.), K. R. Lassey, and R. A. Houghton (Woods Hole Research Center, MA.) 1993 45 p
(NIWA/Atmos/R/93-001; ISBN-0-643-05252-6) Copyright Avail: Issuing Activity

A box-diffusion model is used to calculate the projected atmospheric CO2 concentrations resulting from the various emission scenarios proposed in the 1992 IPCC supplementary report. The terrestrial biota are treated in terms of a release from land-use change and an uptake from enhanced growth so that (1) the contemporary budget balances, and (2) the treatment of the biota in the past is consistent with the approach used in the projections. We refine the modeling by making use of C-14 data to recalibrate the model and translate the calibration uncertainty into estimates of the uncertainties on the projections. We analyze the projections under a range of assumptions that reflect the uncertainties in the current atmospheric carbon budget. We find that the range of uncertainty implies an uncertainty of about +/- 15 percent in the predicted change in CO2 concentrations between 1990 and 2100. Author (revised)
